

The ontological interpretation of informational privacy

Luciano Floridi

E-mail: luciano.floridi@philosophy.oxford.ac.uk

Abstract. The paper outlines a new interpretation of informational privacy and of its moral value. The main theses defended are: (a) informational privacy is a function of the ontological friction in the infosphere, that is, of the forces that oppose the information flow within the space of information; (b) digital ICTs (information and communication technologies) affect the ontological friction by changing the nature of the infosphere (re-ontologization); (c) digital ICTs can therefore both decrease and protect informational privacy but, most importantly, they can also alter its nature and hence our understanding and appreciation of it; (d) a change in our ontological perspective, brought about by digital ICTs, suggests considering each person as being constituted by his or her information and hence regarding a breach of one's informational privacy as a form of aggression towards one's personal identity.

Key words: information ethics, informational privacy, infosphere, ontological friction, personal identity

20 Introduction

“One of these days d’you think you’ll be able to see things at the end of the telephone?” Peggy said, getting up.” She will not return to her wondering again, in the remaining pages of Virginia Woolf’s *The Years*. The novel was published in 1937. Only a year earlier, the BBC had launched the world’s first public television service in London, and Alan Turing had published his groundbreaking work on Turing Machines (Turing, 1936).

Distracted by a technology that invites practical usage more readily than critical reflection, Peggy only half-perceives that new ICTs (information and communication technologies) are transforming society profoundly and irrevocably. The thirties were laying the foundations of the information society. It was difficult to make complete sense of such a significant change in human history, at this early stage of its development. Nevertheless, an evocative phrase concerning the topic of this article appears in an essay on Montaigne, again by Virginia Woolf (*The Common Reader*, 1925): “[we], who have a private life and hold it infinitely the dearest of our possessions [...]”, will find protecting it ever more difficult in a social environment increasingly dependent on Peggy’s futuristic technology.

Today, the commodification of ICTs, begun in the seventies, and the consequent spread of a global

information society since the eighties, are progressively challenging the right to informational privacy, at least as westerners still conceived it in Virginia Woolf’s times. The problem is pressing.¹ It has prompted a stream of scholarly and scientific investigations, witness this special issue of *Ethics and Information Technology*; and there has been no shortage of political decisions and legally enforceable measures to tackle it.² The goal of this paper, however, is not to review the very extensive body of literature dedicated to informational privacy and its legal protection, even in the relatively limited area of computer ethics studies. Rather, it is to argue in favour of a new ontological interpretation of informational privacy and of its moral value, on the basis of the conceptual frame provided by Information Ethics (Floridi, 1999; forthcoming-a).

Informational privacy and computer ethics

Why have digital ICTs made informational privacy one of the most obvious and pressing issues in computer ethics? The question is crucial³ and deceptively simple.

¹ Especially in the US, see Garfinkel (2000).

² Froomkin (2000) still provides a valuable review.

³ See for example Johnson (2001), Bynum and Rogerson (2004) and Tavani (2003).

70	According to one of the most widely accepted	in the very nature (ontology) of the informational	124
71	explanations, digital ICTs exacerbate old problems	environment, of the informational agents ⁴ embedded	125
72	concerning informational privacy because of the	in it and of their interactions. As will be argued in this	126

121	The new challenges posed by digital ICTs are not	in a given environment, e.g. by establishing and	172
122	only a matter of “more of the same”. They have their		
123	roots in a radical and unprecedented transformation		

⁴ For a precise definition of agent see Floridi and Sanders (2004b).

173 maintaining channels of communication and by
 174 overcoming obstacles in the flow of information such
 175 as distance, noise, lack of resources (especially time
 176 and memory), amount and complexity of the data to
 177 be processed etc.

178 Of course, the informational affordances and
 179 constraints provided by an environment are such only
 180 in relation to agents with specific informational
 181 capacities. In our model, brick walls provide much
 182 higher “ontological friction” for the flow of acoustic
 183 information than a paper-thin partition, but this is
 184 irrelevant if the students are deaf. More realistically,
 185 the debate on privacy issues in connection with the
 186 design of office spaces (from private offices to panel-
 187 based open plan office systems, to completely open
 188 working environments, see Becker and Sims (2000))
 189 offers a significant example of the relevance of vary-
 190 ing degrees of ontological friction in social contexts.

191 We are now ready to formulate a qualitative sort
 192 of equation, which will be needed to analyze the
 193 relation between digital ICTs and informational pri-
 194 vacy. Given a certain amount of personal informa-
 195 tion available in (a region of) the infosphere *I*, the
 196 lower the ontological friction in *I*, the higher the
 197 accessibility of personal information about the agents
 198 embedded in *I*, the smaller the informational gap
 199 among them, and the lower the level of informational
 200 privacy implementable about each of them. Put sim-
 201 ply, *informational privacy is a function of the onto-*
 202 *logical friction in the infosphere.* It follows that any
 203 factor affecting the latter will also affect the former.

204 The factors in question can vary and may concern
 205 more or less temporary or reversible changes in the
 206 environment (imagine three of our students living in a
 207 tent during a holiday, while the fourth is left home
 208 alone) or in the agents (e.g., two of our students
 209 change their behaviour because the other two have
 210 quarrelled).

211 Because of their “data superconductivity”, ICTs
 212 are well-known for being among the most influential
 213 factors that affect the ontological friction in the inf-
 214 osphere.⁵ A crucial difference between old and new
 215 ICTs is *how* they affect it.

216 **Ontological friction and the difference between old**
 217 **and new ICTs**

218 In the past, ICTs have always tended to reduce what
 219 agents considered the normal degree of ontological
 220 friction in their environment. This already held true

for the invention of the alphabet or the diffusion of 221
 printing. Photography and the rise of the daily press 222
 were no exceptions. One can easily sympathize with 223
 nineteenth century concerns about the impact on 224
 individuals’ informational privacy of “[r]ecent 225
 inventions and business methods [...], [i]nstantaneous 226
 photographs and newspaper enterprise [...] 227
 and numerous mechanical devices” (Warren and 228
 Brandeis, 1890). 229

230 All this does not mean that, throughout history, 230
 informational privacy has constantly decreased in 231
 relation to the invention and spreading of ever more 232
 powerful ICTs. This would be a simplistic and mis- 233
 taken inference. As emphasized above, changes in the 234
 nature both of the environment and of the agents 235
 play a pivotal role as well, so the actual ontological 236
 friction, and hence the corresponding degree of 237
 informational privacy in a region of the infosphere, 238
 are the result of a fine balance among several factors. 239
 Most notably, during the nineteenth and the twenti- 240
 eth centuries, following the industrial revolution, the 241
 social phenomenon of the new metropolis counter- 242
 acted the effects of the latest ICTs, as urban envi- 243
 ronments fostered a type of informational privacy 244
 based on *anonymity*.⁶ This is the sort of privacy 245
 enjoyed by a leaf in the forest, still inconceivable 246
 nowadays in rural settings or small villages. In the 247
 same period in which Warren and Brandeis were 248
 working on their classic article, the Edinburgh of Dr. 249
 Jekyll⁷ and the London of Sherlock Holmes⁸ already 250
 provided increasing opportunities for informational 251
 privacy through anonymity, despite the recent avail- 252
 ability of new technologies. 253

254 Old ICTs have always tended to reduce the onto- 254
 logical friction in the infosphere because they *enhance* 255
 or *augment* the agents embedded in it. To understand 256
 why, consider the appliances available in our stu- 257
 dents’ house. 258

259 Some appliances – e.g. a drill, a vacuum cleaner or 259
 a food mixer – are tools that *enhance* their users, 260
 exactly like an artificial limb. Tele-ICTs (e.g. the 261
 telescope, the telegraph, the radio, the telephone or 262
 the television) are enhancing in this sense. Some other 263
 appliances – e.g. a dishwasher, a washing machine or 264
 a refrigerator – are robots that *augment* their users 265
 insofar as well-specified tasks can be delegated to 266
 them, at least partially. Recording ICTs (e.g. the 267
 alphabet and the various writing and printing 268

⁶ Anonymity is defined here as the unavailability of personal information, or the “noncoordinability of traits in a given respect”, according to Wallace (1999).

⁷ Stevenson’s *The Strange Case of Dr Jekyll and Mr Hyde* was first published in 1886.

⁸ Doyle’s *A Study in Scarlet* was first published in 1887.

⁵ For a similar point see Moor (1997), who writes “When information is computerized, it is *greased* to slide easily and quickly to many ports of call” (p. 27).

269 technologies, the tape or video recorder) are
270 augmenting in this sense.

271 Enhancing and augmenting ICTs have converged
272 and become bundled together. The Watergate scandal
273 and Nixon's resignation would have been impossible
274 without them. But whether kept separate or packaged
275 together, old ICTs have always shared the funda-
276 mental feature of facilitating the information flow in
277 the infosphere by increasingly empowering the agents
278 embedded in it. This "agent-oriented" trend in old,
279 predigital⁹ ICTs is well represented by dystopian
280 views of informationally omnipotent agents, able to
281 overcome any ontological friction, to control every
282 aspect of the information flow, to acquire any per-
283 sonal data and hence to implement the ultimate sur-
284 veillance system, thus destroying all informational
285 privacy, "the dearest of our possessions".

286 Now, according to a "continuist" interpretation of
287 technological changes, digital ICTs should be treated
288 as just one more instance of well-known, enhancing
289 or augmenting ICTs. But then – the reasoning goes –
290 if there is no radical difference between old and new
291 (i.e. digital) ICTs, it is reasonable to argue that the
292 latter cause increasing problems for informational
293 privacy merely because they are orders of magnitude
294 more powerful than past technologies in enhancing or
295 augmenting agents in the infosphere. All past ICTs
296 have tended to reduce the ontological friction in the
297 infosphere by enhancing or augmenting the agents
298 inhabiting it, but digital ICTs are no exception, so the
299 2P2Q explanation is correct. Orwell's "Big Brother"
300 is readily associated with the ultimate database.

301 Although the continuist 2P2Q hypothesis is rea-
302 sonable and intuitive, it overlooks the essence of the
303 problem. In theory, ontological friction can both be
304 reduced and increased. We have seen how the emer-
305 gence of the urban environment actually produced
306 more anonymity, and hence more ontological friction
307 and more informational privacy. The difference
308 between old and new ICTs is that the former tended
309 to reduce informational privacy, whereas the latter
310 can also increase it. This is because the former tended
311 to enhance or augment the agents involved more and
312 more, whereas the latter can also change the very
313 nature of the infosphere (that is, of the environment
314 itself, of the agents embedded in it and of their
315 interactions). The 2P2Q explanation misses a funda-
316 mental difference between old and new ICTs: the
317 former are enhancing or augmenting whereas the
318 latter are best understood as re-ontologizing tech-
319 nologies, an important distinction that needs to be
320 analyzed in some detail.

Digital ICTs as re-ontologizing technologies

321

Our model and a bit of science fiction will help to
introduce the new concept of *re-ontologization*.¹⁰

Suppose that all the walls and the furniture in our
students' house are transformed into perfectly trans-
parent glass. Assuming our students have good sight,
this will drastically reduce the ontological friction in
the system. Imagine next that the students are
transformed into proficient mind-readers and telep-
athists. Any informational privacy in this sort of
Bentham's *PanOpticon* will become virtually impos-
sible. The thought experiment illustrates how radical
modifications in the very nature (a re-ontologization)
of the infosphere can dramatically change the con-
ditions of possibility of informational privacy.

The influence exercised by the new digital ICTs on
the infosphere can now be analyzed in terms of its re-
ontologization. Schematically, one can distinguish
five fundamental trends.

1. *The digitization of the informational environment.*
This is the most obvious way in which the new ICTs
have re-ontologized the infosphere. The transition
from analogue to digital data is very familiar and
requires no explanation, but perhaps a brief comment
may not go amiss. In their second study on infor-
mation storage and flows, Lyman and Varian (2003)
write that "Print, film, magnetic, and optical storage
media produced about 5 exabytes of new information
in 2002. Ninety-two percent of the new information
was stored on magnetic media, mostly in hard disks.
[...] Five exabytes of information is equivalent in size
to the information contained in 37,000 new libraries
the size of the Library of Congress book collections"
(Lyman and Varian, 2003). Although the production
of analogue data is still increasing, the infosphere is
fast becoming progressively more digital.

2. *The homogenization of the processor and the
processed.* The re-ontologization of the infosphere
has also been caused by the fundamental convergence
between digital resources and digital tools. The
ontology of the information technologies available
(e.g. software, databases, communication protocols
etc.) is now the same as (and hence fully compatible
with) the ontology of their objects. This was one of
Turing's most consequential intuitions: in the re-
ontologized infosphere, there is no longer any sub-
stantial difference between the processor and the
processed and the digital deals effortlessly and
seamlessly with the digital. This potentially eliminates
one of the most long-standing bottlenecks in the
infosphere, a major source of ontological friction.

⁹ Orwell's 1984, first published in 1949, contains no reference to computers or digital machines.

¹⁰ The neologism is constructed following the word "re-engineering" ("to design and construct anew").

372 The increasing computerization of artefacts (from the
 373 cash machine to the fridge, from the car to
 374 the building, from one's underwear to a book, cf. the
 375 current debate on privacy and RFID¹¹ and of whole
 376 social environments (the phenomenon of "Ubiqui-
 377 tous Computing" or "Ambient Intelligence"¹²)
 378 reminds us that soon it will be difficult to understand
 379 what life was in predigital times.

380 3. *The evolution of new informational agents.* This
 381 change concerns the emergence of artificial and
 382 hybrid agents (i.e. partly artificial and partly human;
 383 consider the group of our students as a single agent,
 384 equipped with digital cameras, laptops, palm pilots,
 385 mobiles, a wireless network, digital TVs, DVDs, CD
 386 players, etc.). These new artificial agents share the
 387 same ontology with their environment and can
 388 operate in it with much more freedom and control.
 389 This is where digital ICTs can be mistaken for mere
 390 *augmenting* technologies. Arguably, the infosphere
 391 will be progressively populated by artificial or hybrid
 392 agents, to which other (not necessarily human) agents
 393 will be able to delegate tasks and decisions. It is to be
 394 expected that the moral status of such agents will
 395 become an ever more challenging issue.¹³

396 4. *The informationalization of interactions.* In the
 397 re-ontologized infosphere populated by ontologically-
 398 equal entities and agents, where there is no ontological
 399 difference between processors and processed, inter-
 400 actions become equally digital. They are all inter-
 401 pretable as "read/write" (i.e., access/alter) activities,
 402 with "execute" the remaining type of process.

403 5. The mutation of old agents into informational
 404 agents. Finally, by re-ontologizing the infosphere,
 405 digital ICTs have also brought to light the intrinsi-
 406 cally informational nature of human agents. This is
 407 not equivalent to saying that our students in the
 408 house have digital alter egos, some Messrs Hydes
 409 represented by their @s, blogs and https. This trivial
 410 point only encourages us to mistake digital ICTs for
 411 merely *enhancing* technologies. The informational
 412 nature of agents should not be confused with a "data
 413 shadow"¹⁴ either. The more radical change, brought
 414 about by the re-ontologization of the infosphere, has
 415 been the disclosure of human agents as informational

entities among other informational entities, in the 416
 following sense. 417

Recall the distinction between enhancing and 418
 augmenting appliances. The switches and dials of the 419
 former are interfaces meant to plug in the appliance 420
 to the user's body ergonomically. The data and 421
 control panels of augmenting appliances are instead 422
 interfaces between different possible worlds: on the 423
 one hand there is the human user's *Umwelt*,¹⁵ and on 424
 the other hand there are the dynamic, watery, soapy, 425
 hot and dark world of the dishwasher; the equally 426
 watery, soapy, hot and dark but also spinning world 427
 of the washing machine; or the still, aseptic, soapless, 428
 cold and potentially luminous world of the refriger- 429
 ator. These robots can be successful because they 430
 have their environments "wrapped" and tailored 431
 around their capacities, not vice versa. Imagine our 432
 students trying to build a droid like C3PO capable of 433
 washing their dishes in the sink exactly in the same 434
 way as they would. 435

Computers and digital ICTs are not augmenting or 436
 empowering in the sense just explained. They are 437
 ontologizing devices because they engineer environ- 438
 ments that the user is then enabled to enter through 439
 (possibly friendly) gateways. So, whilst a dishwasher 440
 interface is a panel through which the machine enters 441
 into the user's world, a computer interface is a gate 442
 through which a user can be telepresent in the info- 443
 sphere (Floridi, forthcoming-b). This simple but 444
 fundamental difference underlies the many spatial 445
 metaphors of "cyberspace", "virtual reality", "being 446
 online", "surfing the web", "gateway" and so forth. 447

The re-ontologization of the infosphere, just sket- 448
 ched, has been causing an epochal, unprecedented 449
 migration of humanity from its *Umwelt* to the info- 450
 sphere itself. Inside it, humans are informational 451
 agents among other informational (possibly artificial) 452
 agents. They operate in an environment that is 453
 friendlier to "digital creatures". They have the 454
 ontological status of informational entities. And as 455
 digital immigrants are replaced by digital natives, the 456
 latter may come to appreciate that there is no onto- 457
 logical difference between infosphere and *Umwelt*, 458
 only a difference of levels of abstractions (Floridi and 459
 Sanders, 2004a; forthcoming). 460

**Informational privacy in the re-ontologized 461
 infosphere 462**

To summarize, so far it has been argued that infor- 463
 mational privacy is a function of the ontological 464
 friction in the infosphere. Many factors can affect the 465

¹¹ Radio Frequency IDentification, a method of storing and remotely retrieving data using tags or transponders.

¹² Coroama et al. (2004), Bohn et al. (2004) and Brey (2005) offer an ethical evaluation of privacy-related issues in Ambient Intelligence environments. For a technically informative and balanced assessment see also Gow (2005).

¹³ The issue of artificial morality is analyzed in Floridi and Sanders (2004b).

¹⁴ The term is introduced by Westin (1968) to describe a digital profile generated from data concerning a user's habits online.

¹⁵ The outer world, or reality, as it affects the agent inhabiting it.

466 latter, including, most importantly, technological
467 innovations and social developments. Old ICTs
468 affected the ontological friction in the infosphere
469 mainly by enhancing or augmenting the agents
470 embedded into it; therefore, they tended to decrease
471 the degree of informational privacy possible within
472 the infosphere. On the contrary, digital ICTs
473 affect the ontological friction in the infosphere most
474 significantly by re-ontologizing it; therefore, not only
475 can they both decrease and protect informational
476 privacy but, most importantly, they can also alter its
477 nature and hence our understanding and appreciation
478 of it.

479 Framing the revolutionary nature of digital ICTs
480 in this ontological way offers several advantages. The
481 first can be highlighted immediately: the ontological
482 hypothesis is perfectly consistent with the 2P2Q
483 hypothesis, since the re-ontologization of the info-
484 sphere explains why digital ICTs are so successful, in
485 terms of the quantity, quality and speed at which they
486 can variously process their data. It follows that the
487 ontological hypothesis can inherit whatever explan-
488 atory benefits are carried by the 2P2Q hypothesis.

489 Four other advantages can be listed here but each
490 of them requires a more detailed analysis: (1) con-
491 trary to the 2P2Q hypothesis, the new approach
492 explains why digital ICTs can also enhance infor-
493 mational privacy, although (2) there is still a sense in
494 which the information society provides less protec-
495 tion for informational privacy than the industrial
496 society did. Above all, (3) the ontological hypothesis
497 provides the right frame within which to assess con-
498 temporary interpretations of informational privacy
499 and (4) can indicate how we might wish to proceed in
500 the future in order to protect informational privacy in
501 the newly re-ontologized infosphere. Let us consider
502 each point in turn.

503 **Empowering the informational agent**

504 In the re-ontologized infosphere, any informational
505 agent has an increased power not only to gather and
506 process personal data, but also to control and protect
507 them. Recall that the digital now deals with the dig-
508 ital effortlessly. The phenomenon cuts both ways. It
509 has led not only to a huge expansion in the flow of
510 personal information being recorded, processed and
511 exploited, but also to a large increase in the types and
512 levels of control that agents can exercise on their
513 personal data. And while there is only a certain
514 amount of personal data that an agent may care to
515 protect, the potential growth of digital means and
516 measures to control their life-cycle does not seem to
517 have a foreseeable limit. If privacy is the right of

individuals (being these single persons, groups, or 518
institutions) to control the life-cycle (especially the 519
generation, access, recording and usage) of their 520
information and determine for themselves when, 521
how, and to what extent their information is pro- 522
cessed by others, then one must agree that digital 523
ICTs may enhance as well as hinder the possibility of 524
enforcing such right. 525

At their point of generation, digital ICTs can 526
foster the protection of personal data, e.g. by means 527
of encryption, anonymization, password-encoding, 528
firewalling, specifically devised protocols or services, 529
and, in the case of externally captured data, warning 530
systems. 531

At their point of storage, legislation, such as the 532
Data Protection Directive passed by the EU in 1995, 533
guarantees that no ontological friction, already 534
removed by digital ICTs, is surreptitiously reintro- 535
duced to prevent agents from coming to know about 536
the existence of personal data records, and from 537
accessing them, checking their accuracy, correcting or 538
upgrading them or demanding their erasure. 539

And at their point of exploitation – especially 540
through data-mining, -sharing, -matching and 541
-merging – digital ICTs could help agents to control 542
and regulate the usage of their data by facilitating the 543
identification and regulation of the relevant users 544
involved. 545

At each of these three stages, solutions to the 546
problem of protecting informational privacy can be 547
not only self-regulatory and legislative but also 548
technological, not least because informational pri- 549
vacy infringements can more easily be identified and 550
redressed also thanks to digital ICTs. 551

All this is not to say that we are inevitably moving 552
towards an idyllic scenario in which our PETs (Pri- 553
vacy Enhancing Technologies) will fully protect our 554
private lives and information against harmful PITs 555
(Privacy Intruding Technologies). Such optimism is 556
unjustified. But it does mean that digital ICTs can 557
already provide some means to counterbalance the 558
risks and challenges that they represent for informa- 559
tional privacy, and hence that no fatalistic pessimism 560
is justified either. Digital ICTs do not necessarily 561
erode informational privacy; they can also enhance 562
and protect it. A good example is provided by the 563
P3P (Platform for Privacy Preferences) initiative of 564
the W3C (World Wide Web Consortium, see [http://](http://www.w3.org/P3P/) 565
www.w3.org/P3P/). 566

The return of the (digital) community 567

Because digital ICTs are radically modifying our 568
informational environments, ourselves and our 569

570 interactions, it would be naïve to expect that infor- 600
 571 mational privacy in the future will mean exactly what 601
 572 it meant in the industrial Western world in the middle 602
 573 of the last century. 603

574 In section four, we saw that, between the end of 604
 575 the nineteenth and the beginning of the twentieth 605
 576 century, the ontological friction in the infosphere, 606
 577 actually reduced by old ICTs, was nevertheless 607
 578 increased by social conditions favouring anonymity 608
 579 and hence a new form of informational privacy. In 609
 580 this respect, the diffusion of digital ICTs has finally 610
 581 brought to completion the process begun with the 611
 582 invention of printing. We are back into the now 612
 583 digital community, where anonymity can no longer 613
 584 be taken for granted, and hence where the decrease in 614
 585 ontological friction caused by old and new ICTs can 615
 586 have all its full-blown effects on informational pri- 616
 587 vacy. In Britain, for example, public places are con- 617
 588 stantly monitored by 1.5 m CCTV systems, with the 618
 589 result that the average citizen is recorded 300 times a 619
 590 day (The Economist, (Jan 23rd 2003). The digital 620
 591 ICTs that allowed terrorists to communicate undis- 621
 592 turbed over the Internet were also responsible for the 622
 593 identification of the London bombers in a matter of 623
 594 hours (Figure 1). Likewise, mobile phones are 624
 595 increasingly useful as forensic evidence in trials. In 625
 596 Britain, cell site analysis (a form of triangulation that 626
 597 estimates the location of a mobile phone when it is 627
 598 used) helped disprove Ian Huntley’s alibi and convict 628
 599 him for the murdering of Holly Wells and Jessica 629

Chapman. Sherlock Holmes has the means to fight 600
 Mr. Hyde. 601

602 How serious and dangerous is it to live in a glassy 602
 603 infosphere? Human agents tend to be acquainted with 603
 604 different environments that have varying degrees of 604
 605 ontological friction and hence to be rather good at 605
 606 adapting themselves accordingly. As with other forms 606
 607 of fine equilibria, it is hard to identify, for all agents 607
 608 in any environments, a common, lowest threshold of 608
 609 ontological friction below which human life becomes 609
 610 increasingly unpleasant and ultimately unbearable. It 610
 611 is clear, however, that a particular threshold has been 611
 612 overcome when the agents are willing to employ 612
 613 resources, run risks or expend energy to restore it, e.g. 613
 614 by building a higher fence, by renouncing a desired 614
 615 service, or by investing time in revising a customer 615
 616 profile. On the other hand, different agents have 616
 617 different degrees of sensitivity. One needs to remem- 617
 618 ber that several factors (character, culture, upbringing, 618
 619 past experiences etc.) make each agent a unique 619
 620 individual. To one person, a neighbour capable of 620
 621 seeing one’s garbage in the garden may seem an 621
 622 unbearable breach of their privacy, which it is worth 622
 623 any expenditure and effort to restore; to another 623
 624 person, living in the same room with several other 624
 625 family members may feel entirely unproblematic. 625
 626 Human agents can adapt to very low levels of onto- 626
 627 logical friction. Virginia Woolf’s essay on Montaigne 627
 628 discusses the lack of ontological friction that char- 628
 629 acterizes public figures in public contexts. Politicians 629

Figure 1. CCTV image of the four London terrorists as they set out from Luton.

630 and actors are used to environments where privacy is a
631 rare commodity. Likewise, people involved in “Big
632 Brother” (but “Truman Show” would be a more
633 appropriate label) programmes show a remarkable
634 capacity to adapt to settings where any ontological
635 friction between them and the public is systematically
636 reduced, apparently for the sake of entertainment. In
637 far more tragic and realistic contexts, prisoners in
638 concentration camps are subject to extreme duress
639 due to both intended and unavoidable rarefaction of
640 ontological friction (Levi, 1959).

641 The information society has revised the threshold
642 of ontological friction and therefore provides a dif-
643 ferent sense in which its citizens appreciate their
644 informational privacy. Your supermarket knows
645 exactly what you like, but so did the owner of the
646 grocery where your grandparents used to shop. Your
647 bank has detailed records of all your visits and of
648 your financial situation, but how exactly is this dif-
649 ferent from the old service? A phone company could
650 analyze and transform the call data collected for
651 billing purposes into a detailed subscriber profile:
652 social network (names and addresses of colleagues
653 friends or relatives called), possible nationality (types
654 of international calls), times when one is likely to be
655 at home and hence working patterns, financial profile
656 (expenditure) and so forth. Put together the data
657 from the supermarket, the bank and the phone
658 company, and inferences of all sorts could be drawn
659 for one’s credit rating. Yet so they could be and were
660 in Alexandre Dumas’ *The Count of Monte Cristo*
661 (1844). *Some* steps forward into the information
662 society are really steps back into a small community
663 and, admittedly, the claustrophobic atmosphere that
664 may characterize it.

665 In the early stages in the history of the Web,
666 roughly when Netscape was synonymous with
667 browser, users believed that being online meant being
668 entirely anonymous. A networked computer was like
669 Gyges’ ring in Plato’s *Republic* (359b–360d): it made
670 one invisible, unaccountable and therefore potentially
671 less responsible, socially speaking. Turing would
672 certainly have appreciated the (at the time) popular
673 comic strip in which a dog, typing an email on a
674 computer, confessed to another dog that “when you
675 are on the Internet nobody can guess who you are”.
676 Nowadays, the strip is not funny anymore, only
677 outdated. Cookies, monitoring software and malware
678 (malicious software, such as spyware) have made
679 people realize that the screen in front of them is not a
680 shield for their privacy or Harry Potter’s invisibility
681 cloth, but a window on their lives online, through
682 which virtually anything could be seen. They expect
683 web sites to monitor and record their activities and do
684 not even mind for what purpose. They accept that

being online is one of the less private things in life.¹⁶ 685
The screen is a monitor and is monitoring you. 686

A few years ago, a journalist at *The Economist* ran 687
an experiment (*The Economist*, December 16th 1999). 688
He asked a private investigator, “Sam”, to show what 689
information it was possible to gather about someone. 690
The journalist himself was to be the subject of the 691
experiment. The country was Britain, the place where 692
the journalist lived. The journalist provided Sam with 693
only his first and last names. Sam was told not to use 694
“any real skulduggery (surveillance, going through 695
her domestic rubbish, phone-tapping, hacking, that 696
sort of thing)”. The conclusion? By using several 697
databases and various ICTs, “Without even talking to 698
anyone who knows me, Sam [...] had found out quite 699
a bit about me. He had a reasonable idea of my per- 700
sonal finances – the value of my house, my salary and 701
the amount outstanding on my mortgage. He knew 702
my address, my phone number, my partner’s name, a 703
former partner’s name, my mother’s name and 704
address, and the names of three other people who had 705
lived in my house. He had ‘found’ my employer. He 706
also had the names and addresses of four people who 707
had been directors of a company with me. He knew 708
my neighbours’ names.” 709

Shocking? Yes, in the anonymous industrial soci- 710
ety, but not really in the pre-industrial village before 711
it, or in the information society after it. In Guarino, 712
a small village south of Rome of roughly a thousand 713
people, everybody knows everything about every- 714
body else, “vita, morte e miracoli”, “life, death and 715
miracles”, as they say in Italian. There is very little 716
ontological friction provided by anonymity so there is 717
very little informational privacy in that respect. A 718
difference with the information society is that we have 719
seen that the latter has the digital means to protect 720
what the small village must necessarily forfeit. 721

There are of course many other dissimilarities. As 722
Paul Oldfield has rightly stressed,¹⁷ the comparison 723
between today’s information society and the small 724
community of the past, where “everybody knows 725
everything”, must be taken with more than a pinch 726
of salt. History may repeat itself, yet never too 727

¹⁶ “The best long-term assessment of public attitudes toward privacy is provided by Columbia’s Alan Westin, who has conducted a series of polls over the last thirty years on this issue. On average, he finds that one quarter of the American public cares deeply about keeping personal information secret, one quarter doesn’t care much at all, and roughly half are in the middle, wanting to know more about the benefits, safeguards, and risks before providing information. Customer behaviour in the marketplace – where many people freely provide personal information in exchange for various offers and benefits – seems to bear out this conclusion” Walker (2000).

¹⁷ Private communication. The rest of this section is largely based on comments sent to me by Paul Oldfield.

728 monotonously. Small communities had a high degree
 729 of intra-community transparency (like a shared
 730 house) but a low degree of inter-community trans-
 731 parency (they were not like the Big Brother house,
 732 visible to outside viewers). So in those communities,
 733 the breaches of privacy were reciprocal, yet there were
 734 few breaches of privacy across the boundary of the
 735 community. This is quite different from today's
 736 information society, where there can be very little
 737 transparency within the communities we live or work
 738 in (we hardly know our neighbours, and our fellow-
 739 workers have their privacy rigorously protected), yet
 740 data-miners, hackers and institutions can be very well
 741 informed about us. Breaches of privacy from outside
 742 are common. What is more, we do not even know
 743 whether they know our business. On the other hand,
 744 part of the value of this comparison lies in the size of
 745 the community taken into consideration. A special
 746 trait of the information society is precisely its lack of
 747 boundaries, its global nature. We live in a single inf-
 748 osphere, which has no "outside" and where intra- and
 749 inter-community relations are more difficult to dis-
 750 tinguish. The types of invasion of privacy are quite
 751 different too. In the small community, breaches of
 752 privacy might shame or discredit you. Interestingly,
 753 Augustine usually speaks of privacy in relation to the
 754 topic of intercourse in married couples, and he always
 755 associates it to secrecy and secrecy to shame or
 756 embarrassment. Or they might disclose your real
 757 identity or character (more on this in section ten).
 758 Things that were private became public knowledge. In
 759 the information society, such breaches involve unau-
 760 thorized collection of information, not necessarily its
 761 publication. Things that are private may not become
 762 public at all; they may be just accessed and used by
 763 privileged others. The small community also had its
 764 own self-regulations for limiting breaches of privacy.
 765 Everyone knew that they were as subject to scrutiny as
 766 everyone else, and this set an unspoken limit on their
 767 enthusiasm for intruding into others' affairs.

768 **Assessing theories of privacy**

769 Once it is acknowledged that digital ICTs have
 770 re-ontologized the infosphere, it becomes easier to
 771 assess the available theories of informational privacy
 772 and its moral value.

773 Two theories are particularly popular: the *reduc-*
 774 *tionist interpretation* and the *ownership-based*
 775 *interpretation*.

776 The reductionist interpretation argues that the
 777 value of informational privacy rests on a variety of
 778 undesirable consequences that may be caused by its
 779 breach, either personally (e.g. distress) or socially

(e.g. unfairness). Informational privacy is a utility, 780
 also in the sense of providing an essential condition of 781
 possibility of good human interactions, e.g. by pre- 782
 serving human dignity or by providing political 783
 checks and balances. 784

The ownership-based interpretation argues that 785
 informational privacy needs to be respected because of 786
 each person's rights to bodily security and property 787
 (where "property of x" is classically understood as the 788
 right to exclusive use of x). A person is said to *own* his 789
 or her information (information about him- or herself) 790
 – recall Virginia Woolf's "infinitely the dearest of our 791
 possessions" – and therefore to be entitled to control 792
 its whole life-cycle, from generation to erasure.¹⁸ 793

The two approaches are not incompatible, but 794
 they stress different aspects of informational privacy. 795
 One is more oriented towards a consequentialist 796
 assessment of privacy protection or violation. The 797
 other is more oriented towards a "natural rights" 798
 understanding of the concept of privacy itself, in 799
 terms of private or intellectual property. Unsurpris- 800
 ingly, they both compare privacy breach to a tres- 801
 pass¹⁹ or unauthorized invasion of, or intrusion in, a 802
 space or sphere of personal information, whose 803
 accessibility and usage ought to be fully controlled by 804
 its owner and hence kept private. A typical example is 805
 provided by the border-crossing model of informa- 806
 tional privacy developed by Gary T. Marx since the 807
 late nineties (see now Marx, 2005). 808

The reductionist interpretation is not entirely sat- 809
 isfactory. Defending the need for respect for infor- 810
 mational privacy in view of the potential misuse of 811
 the information acquired is certainly reasonable, 812
 especially from a consequentialist perspective, but it 813
 may be inconsistent with pursuing and furthering 814
 social interests and welfare. For, although it is obvi- 815
 ous that even some public personal information may 816
 need to be protected – e.g. against profiling or unre- 817
 strained electronic surveillance – it remains unclear, 818
 on a purely reductionist basis, whether a society 819
 devoid of any informational privacy may not be a 820
 better society, with a higher, common welfare.²⁰ It 821

¹⁸ The debate on the ownership-based interpretation developed in the seventies, see Scanlon (1975) and Rachels (1975), who criticize Thomson (1975), who supported an interpretation of the right to privacy as being based on property rights.

¹⁹ See Spinello (2005) for a recent assessment of the use of the trespassing analogy in computer-ethical and legal contexts. Charles Ess has pointed out to me that comparative studies have shown such spatial metaphors to be popular only in Western contexts.

²⁰ Moor (1997) infers from this that informational privacy is not a core value, i.e. a value that "all normal humans and cultures need for survival", but then other values he lists as "core" are not really so in his sense, e.g. happiness and freedom. According to Moor, privacy is also intrinsically valuable, while being the expression of the core value represented by security.

822 has been argued, for example, that the defence of
 823 informational privacy in the home may actually be
 824 used as a subterfuge to hide the dark side of privacy:
 825 domestic abuse, neglect or mistreatment. Precisely
 826 because of reductionist-only considerations, even in
 827 democratic societies such as the UK and the US, it
 828 tends to be acknowledged that the right to informa-
 829 tional privacy can be overridden when other concerns
 830 and priorities, including business needs, public safety
 831 and national security, become more pressing. All this
 832 is despite the fact that article 12 of *The Universal*
 833 *Declaration of Human Rights* clearly indicates that
 834 “No one shall be subjected to arbitrary interference
 835 with his privacy, family, home or correspondence,
 836 nor to attacks upon his honour and reputation.
 837 Everyone has the right to the protection of the law
 838 against such interference or attacks.”

839 The ownership-based interpretation also falls short
 840 of being entirely satisfactory. Three problems are
 841 worth highlighting here:

- 842 (i) the issue of informational contamination under-
 843 mining passive informational privacy; this is the
 844 unwilling acquisition of information or data (e.g.
 845 mere noise) imposed on someone by some external
 846 source. Brainwashing may not occur often, but
 847 junkmail, or the case of a person chatting loudly
 848 on a mobile near us, are unfortunately very com-
 849 mon experiences of passive privacy breach, yet no
 850 informational ownership seems to be violated;
- 851 (ii) the issue of informational privacy in public con-
 852 texts; informational privacy is often exercised in
 853 public spaces, that is, in spaces which are not only
 854 socially and physically public – a street, a car
 855 park, a pub – but also informationally public –
 856 anyone can see the newspaper one buys, the bus
 857 one takes, the T-shirt one wears, the drink one is
 858 ordering (Patton, 2000). How could a CCTV
 859 system be a breach of someone’s privacy if the
 860 agent is accessing a space which is public in all
 861 possible senses anyway? and
- 862 (iii) the metaphorical and imprecise use of the concept
 863 of “information ownership”, which cannot quite
 864 explain the lossless acquisition (or usage) of
 865 information: contrary to other things that one
 866 owns, one’s personal information is not lost when
 867 acquired by someone else. Analyses of privacy
 868 based on “ownership” of an “informational
 869 space” are metaphorical twice over.

870 **The ontological interpretation of informational**
 871 **privacy and its value**

872 Both the reductionist and the ownership-based
 873 interpretation fail to acknowledge the radical change

874 brought about by digital ICTs. They belong to an
 875 industrial culture of material goods and of manu-
 876 facturing/trading relations. They are overstretched
 877 when trying to cope with the new challenges offered
 878 by an informational culture of services and usability.

879 Warren and Brandeis (1890) had already realized
 880 this limit very insightfully: “where the value of the
 881 production [of some information] is found not in the
 882 right to take the profits arising from publication, but
 883 in the peace of mind or the relief afforded by the
 884 ability to prevent any publication at all, *it is difficult*
 885 *to regard the right as one of property, in the common*
 886 *acceptation of the term”* (p. 25, emphasis added).

887 More than a century later, in the same way as the
 888 digital revolution is best understood as a fundamental
 889 re-ontologization of the infosphere, informational
 890 privacy requires an equally radical re-interpretation,
 891 one that takes into account the essentially informa-
 892 tional nature of human beings and of their operations
 893 as informational social agents.

894 Such re-interpretation is achieved by considering
 895 each person as constituted by his or her information,
 896 and hence by understanding a breach of one’s infor-
 897 mational privacy as a form of aggression towards
 898 one’s personal identity.

899 The following passage by Marcel Proust, though
 900 admittedly referring to the social construction of the
 901 individual, helps to convey the idea of a person as an
 902 informational entity: “But then, even in the most
 903 insignificant details of our daily life, none of us can be
 904 said to constitute a material whole, which is identical
 905 for everyone, and need only be turned up like a page
 906 in an account-book or the record of a will; our social
 907 personality is created by the thoughts of other people.
 908 Even the simple act which we describe as “seeing
 909 some one we know” is, to some extent, an intellectual
 910 process. We pack the physical outline of the creature
 911 we see with all the ideas we have already formed
 912 about him, and in the complete picture of him which
 913 we compose in our minds those ideas have certainly
 914 the principal place. In the end they come to fill out so
 915 completely the curve of his checks, to follow so
 916 exactly the line of his nose, they blend so harmoni-
 917 ously in the sound of his voice that these seem to be
 918 no more than a transparent envelope, so that each
 919 time we see the face or hear the voice it is our own
 920 ideas of him which we recognize and to which we
 921 listen.” (*Remembrance of Things Past – Swann’s*
 922 *Way*).

923 The ontological interpretation is consistent with
 924 the fact that digital ICTs can both erode and rein-
 925 force informational privacy, and hence that a positive
 926 effort needs to be made in order to support not only
 927 PET but also “poietic” (i.e. constructive) applica-
 928 tions, which may allow users to design, shape and

929 maintain their identities as informational agents
 930 (Floridi and Sanders, 2005). The information flow
 931 needs some friction in order to keep firm the dis-
 932 tinction between the multiagent system (the society)
 933 and the identity of the agents (the individuals) con-
 934 stituting it. Any society (even a utopian one) in which
 935 no informational privacy is possible is one in which
 936 no personal identity can be maintained and hence no
 937 welfare can be achieved, social welfare being only the
 938 sum of the individuals' involved. The total "trans-
 939 parency" of the infosphere that may be advocated by
 940 some reductionists – recall the example of the glassy
 941 house and of our mentally super-enhanced students –
 942 achieves the protection of society only by erasing all
 943 personal identity and individuality, a "final solution"
 944 for sure, but hardly one that the individuals them-
 945 selves, constituting the society so protected, would be
 946 happy to embrace freely.

947 The advantage of the ontological interpretation
 948 over the reductionist one is then that consequentialist
 949 concerns may override respect for informational
 950 privacy, whereas the ontological interpretation, by
 951 equating its protection to the protection of personal
 952 identity, considers it a fundamental and inalienable
 953 right,²¹ so that, by default, the presumption should
 954 always be in favour of its respect. As we shall see, this
 955 is not to say that informational privacy is never
 956 negotiable in any degree.

957 Looking at the nature of a person as being con-
 958 stituted by that person's information allows one to
 959 understand the right to informational privacy as a
 960 right to personal immunity from unknown, undesired
 961 or unintentional changes in one's own identity as an
 962 informational entity, either actively – collecting,
 963 storing, reproducing, manipulating etc. one's infor-
 964 mation amounts now to stages in cloning and
 965 breeding someone's personal identity – or passively –
 966 as breaching one's informational privacy may now
 967 consist in forcing someone to acquire unwanted data,
 968 thus altering her or his nature as an informational
 969 entity without consent.²² The first difficulty facing the
 970 ownership-based interpretation is thus avoided: in
 971 either case, the ontological interpretation suggests
 972 that there is no difference between one's informa-
 973 tional sphere and one's personal identity. "You are
 974 your information", so anything done to your infor-
 975 mation is done to you, not to your belongings. The
 976 right to informational privacy (both in the active and
 977 in the passive sense just seen) shields one's personal
 978 identity. This is why informational privacy is extre-
 979 mely valuable and ought to be respected.

Heuristically, violations of informational privacy 980
 are now more fruitfully compared to a digital kid- 981
 napping rather than trespassing: the observed is 982
 moved to an observer's local space of observation (a 983
 space which is remote for the observed), unwillingly 984
 and possibly unknowingly. What is abducted is per- 985
 sonal information and no actual removal is in ques- 986
 tion, but a cloning of the relevant piece of personal 987
 information. Yet the cloned information is not a 988
 "space" that belongs to the observed and which has 989
 been trespassed; it is part of the observed herself, or 990
 better something that (at least partly) constitutes the 991
 observed for what she or he is. It is a *Doppelgänger*, 992
 as Richard Avedon described it once, when speaking 993
 of his photograph of Henry Kissinger ("Is it just a 994
 shadow representation of a man? Or is it closer to a 995
 doppelgänger, a likeness with its own life, an inexact 996
 twin whose afterlife may overcome and replace the 997
 original?"). A further advantage, in this change of 998
 perspective, is that it becomes possible to dispose of 999
 the false dichotomy qualifying informational privacy 1000
 in public or in private contexts. Insofar as a piece of 1001
 information constitutes an agent, it does so context- 1002
 independently and that is why the observed may wish 1003
 to preserve her integrity and uniqueness as an infor- 1004
 mational entity, even when she is in an entirely public 1005
 place. After all, trespassing makes no sense in a 1006
 public space, but kidnapping is a crime independently 1007
 of where it is committed. The second problem 1008
 affecting the ownership-based interpretation is also 1009
 solved. 1010

As for the third problem, one may still argue that 1011
 an agent "owns" his or her information, yet no longer 1012
 in the metaphorical sense seen above, but in the 1013
 precise sense in which an agent *is* her or his infor- 1014
 mation. "My" in "my information" is not the same 1015
 "my" as in "my car" but rather the same "my" as in 1016
 "my body" or "my feelings": it expresses a sense of 1017
 constitutive *belonging*, not of external *ownership*, a 1018
 sense in which my body, my feelings and my infor- 1019
 mation are part of me but are not my (legal) pos- 1020
 sessions. It is worth quoting Warren and Brandeis 1021
 (1890) once again: "[...] the protection afforded to 1022
 thoughts, sentiments, and emotions [...] is merely an 1023
 instance of the enforcement of the more general right 1024
 of the individual to be let alone. It is like the right not 1025
 to be assaulted or beaten, the right not to be 1026
 imprisoned, the right not to be maliciously perse- 1027
 cuted, the right not to be defamed [or, the right not to 1028
 be kidnapped, my addition]. In each of these rights 1029
 [...] there inheres the quality of being owned or pos- 1030
 sessed and [...] there may be some propriety in 1031
 speaking of those rights as property. But, obviously, 1032
 they bear little resemblance to what is ordinarily 1033
 comprehended under that term. *The principle [...] is in* 1034

²¹ For a different view see Volkman, 2003.

²² This view is close to the interpretation of privacy in terms of protection of human dignity defended by Bloustein (1964).

1035 *reality not the principle of private propriety but that of*
 1036 *involute personality* (p. 31, emphasis added) [...] *the*
 1037 *right to privacy, as part of the more general right to the*
 1038 *immunity of the person, [is] the right to one's person-*
 1039 *ality* (p. 33, emphasis added).

1040 This ontological conception has started being
 1041 appreciated by more advanced information societies
 1042 where identity theft is the fastest growing white-collar
 1043 offence, as Figure 2 well indicates. Informational
 1044 privacy is the other side of identity theft, to the point
 1045 that, ironically, for every person whose identity has
 1046 been stolen (around 10m Americans are victims
 1047 annually) there is another person (the thief) whose
 1048 identity has been “enhanced”.

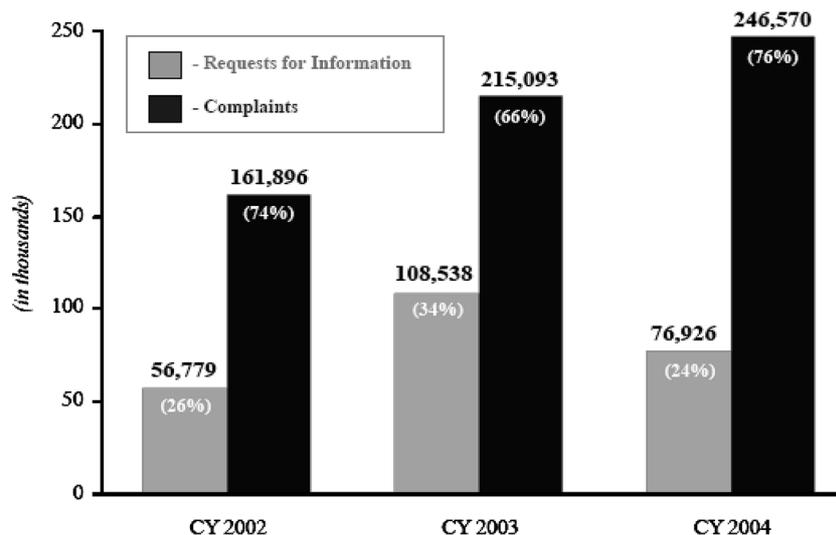

1049 Recent problems affecting Google and its privacy
 1050 policy convey a similar picture. As Kevin Bankston,
 1051 staff attorney at the Electronic Frontier Foundation,
 1052 remarks “Your search history shows your associa-
 1053 tions, beliefs, perhaps your medical problems. *The*
 1054 *things you Google for define you.* [...] data that’s
 1055 practically a printout of what’s going on in your
 1056 brain: What you are thinking of buying, who you talk
 1057 to, what you talk about” (quoted in Mills, 2005,
 1058 emphasis added).

1059 As anticipated, the ontological interpretation
 1060 reshapes some of the assumptions behind our still
 1061 “industrial” conception of informational privacy.
 1062 Three examples are indicative of this transition.

1063 If personal information is finally acknowledged to
 1064 be a constitutive part of someone’s personal identity
 1065 and individuality, then one day it may become strictly
 1066 illegal to trade in some kinds of personal information,
 1067 exactly as it is illegal to trade in human organs
 1068 (including one’s own) or slaves. The problem of child
 1069 pornography may also be revisited in light of an
 1070 ontological interpretation of informational privacy.
 1071 At the same time, one might relax one’s attitude
 1072 towards some kinds of “dead personal information”
 1073 that, like “dead pieces of oneself”, are not really or
 1074 no longer constitutive of oneself. One should not sell
 1075 one’s kidney, but can certainly sell one’s hair or be
 1076 rewarded for giving blood. Recall the experiment of
 1077 the journalist at *The Economist*. Very little of what
 1078 Sam had discovered could be considered ontologi-
 1079 cally constitutive of the person in question. We are
 1080 constantly leaving behind a trail of personal data,
 1081 pretty much in the same sense in which we are losing
 1082 a huge trail of dead cells. The fact that nowadays
 1083 digital ICTs allow our data trails to be recorded,
 1084 monitored, processed and used for social, political or
 1085 commercial purposes is a strong reminder of our
 1086 informational nature as individuals and might be seen
 1087 as a new level of ecologism, as an increase in what is
 1088 recycled and a decrease in what is wasted.

1089 At the moment, all this is just speculation and in
 1090 the future it will probably be a matter of fine
 1091

**Total Identity Theft Records¹
by Calendar Year**

¹Percentages are based on the total number of identity theft records by calendar year.

Figure 2. Identity thefts in the US between 2002 and 2004. Source: Data from Consumer Sentinel and the Identity Theft Data Clearinghouse, National and State Trends in Fraud & Identity Theft, January–December 2004. Federal Trade Commission, February 1, 2005.

1091 adjustments of ethical sensibilities, but the third
 1092 Geneva Convention (1949) already provides a clear
 1093 test of what might be considered “dead personal
 1094 information”: a prisoner of war need only give his or
 1095 her name, rank, date of birth, and serial number and
 1096 no form of coercion may be inflicted on him or her to
 1097 secure any further information, of any kind. If we
 1098 were all considered “prisoners of the information
 1099 society”, our informational privacy would be well
 1100 protected and yet there would still be some personal
 1101 data that would be perfectly fine to share with any
 1102 other agent, even hostile ones.

1103 A further issue that might be illuminated by the
 1104 ontological interpretation is that of confidentiality.
 1105 The sharing of private information with someone,
 1106 implicitly or explicitly, is based on a relation of pro-
 1107 found trust that joins together the agents involved.
 1108 This coupling is achieved by allowing the agents to be
 1109 partly constituted, ontologically, by the same infor-
 1110 mation. Visually, the informational identities of the
 1111 agents involved now overlap, at least partially, as in a
 1112 Venn diagram. The union of the agents forms a single
 1113 unity, a supra-agent. Precisely because entering into a
 1114 new supra-agent is a delicate and risky operation,
 1115 care should be exercised before “melding” oneself
 1116 with other individuals by sharing personal informa-
 1117 tion or its source i.e. common experiences. Confiden-
 1118 tiality is a bond that is hard and slow to forge
 1119 properly, yet resilient to many external forces when
 1120 finally in place, as the supra-agent is stronger than the
 1121 constitutive agents themselves. Relatives, friends,
 1122 classmates, fellows, colleagues, comrades, compan-
 1123 ions, partners, team-mates, spouses and so forth may
 1124 all have experienced the nature of such a bond, the
 1125 stronger taste of a “we”. But it is also a bond very
 1126 brittle and difficult to restore when it comes to
 1127 betrayal, since the disclosure, deliberate or uninten-
 1128 tional, of some personal information in violation of
 1129 confidence can entirely and irrecoverably destroy the
 1130 privacy of the new, supra-agent born out of the
 1131 joining agents, by painfully tearing them apart. We
 1132 shall return to the topic of trust and confidentiality at
 1133 the end of this article.

1134 A third and final issue can be touched upon rather
 1135 briefly, as it was already mentioned above: the
 1136 ontological interpretation stresses that informational
 1137 privacy is also a matter of construction of one’s own
 1138 informational identity. The right to be let alone is
 1139 also the right to be allowed to experiment with one’s
 1140 own life, to start again, without having records that
 1141 mummify one’s personal identity forever, taking
 1142 away from the individual the power to mould it.
 1143 Everyday, a person may wish to build a different,
 1144 possibly better, “I”. We never stop becoming our-
 1145 selves, so protecting a person’s informational privacy

also means allowing that person the freedom to 1146
 change, ontologically.²³ 1147

Informational privacy, personal identity and biometrics 1148

On September 12, 1560 the young Montaigne atten- 1149
 ded the public trial of Arnaud du Tilh, an impostor 1150
 who was sentenced to death for having faked his 1151
 identity. Many acquaintances and family members, 1152
 including the wife Bertrande, had been convinced for 1153
 a long while that he was Martin Guerre, returned 1154
 home after many years of absence. Only when the 1155
 real Martin Guerre came home was Arnaud’s actual 1156
 identity finally ascertained. 1157

Had Martin Guerre always been able to protect his 1158
 personal information, Arnaud du Tilh would have 1159
 been unable to steal his identity. Clearly, the more 1160
 one’s informational privacy is protected the more one’s 1161
 personal identity can be safeguarded. This new quali- 1162
 tative equation is a direct consequence of the onto- 1163
 logical interpretation. Personal identity also depends 1164
 on informational privacy. The difficulty facing our 1165
 contemporary society is how to combine the new 1166
 equation with the other equation, introduced in sec- 1167
 tion three, according to which informational privacy is 1168
 a function of the ontological friction in the infosphere. 1169
 Ideally, one would like to reap all the benefits from 1170

- (a) the highest level of information flow; and hence 1171
 from 1172
- (b) the lowest level of ontological friction; while 1173
 enjoying 1174
- (c) the highest level of informational privacy pro- 1175
 tection; and hence 1176
- (d) the highest level of personal identity protection. 1177

The problem is that (a) and (d) seem incompatible: 1178
 facilitate and increase the information flow through 1179
 digital ICTs and the protection of one’s personal 1180
 identity is bound to come under increasing pressure. 1181
 You cannot have an identity without having an 1182
 identikit. Or so it seems, until one realizes that the 1183
 information flowing in (a) consists of all sorts of data, 1184
 including *arbitrary* data *about* oneself (e.g. a name 1185
 and surname) that are actually shareable, whereas the 1186
 information required to protect (d) can be *ontic* data, 1187
 that is, data *constituting* someone (e.g. someone’s 1188
 DNA) that are hardly sharable by nature.²⁴ Enter 1189
 biometrics. 1190

²³ In this sense, Johnson (2001) seems to be right in considering informational privacy an essential element in an individual’s autonomy. Moor (1997), referring to a previous edition of Johnson (2001), disagrees.

²⁴ On the tripartite distinction between information as, about or for reality see Floridi (2004).

1191 Personal identity is the weakest link and most
 1192 delicate element in our problem. Even nowadays,
 1193 personal identity is regularly protected and authen-
 1194 ticated by means of some *arbitrary* data, *randomly* or
 1195 *conventionally* attached to the bearer/user, like a
 1196 mere label: a name, an address, a Social Security
 1197 number, a bank account, a credit card number, a
 1198 driving licence number, a PIN and so forth. Each
 1199 label in the list has no ontologically constitutive link
 1200 with its bearer; it is merely associated with some-
 1201 one's identity and can easily be detached from it
 1202 without affecting it. The rest is a mere consequence
 1203 of this "detachability". The more the ontological
 1204 friction in the infosphere decreases, the swifter these
 1205 detached labels can flow around, and the easier it
 1206 becomes to grab and steal them and use them for
 1207 illegal purposes. Arnaud du Tilh had stolen a name
 1208 and a profile and succeeded in impersonating Martin
 1209 Guerre for many years in a rather small village,
 1210 within a community that knew him well, fooling
 1211 even Martin's wife, apparently. Eliminate all per-
 1212 sonal interactions and identity theft becomes the
 1213 easiest thing in the world.

1214 A quick and dirty way to fix the problem would be
 1215 to clog the infosphere by slowing down the infor-
 1216 mation flow. Building some traffic calming device, as
 1217 it were. It seems the sort of policy popular among
 1218 some IT officers and bank managers, keen on not
 1219 allowing this or that operation for security reasons,
 1220 for example. However, as with all counter-revolu-
 1221 tionary or anti-historical approaches, "resistance is
 1222 futile": trying to withstand the evolution of the in-
 1223 fosphere only harms current users and, in the long
 1224 run, fails to deliver an effective solution.

1225 A much better approach is to ensure that the
 1226 ontological friction keeps decreasing, thus benefiting
 1227 all the inhabitants of the infosphere, while safe-
 1228 guarding personal identity by data that are not
 1229 arbitrary labels about, but rather constitutive traits
 1230 of, the person in question. Arnaud du Tilh and
 1231 Martin Guerre looked very similar, yet this was as far
 1232 as biometrics went in the sixteenth century. Today,
 1233 biometric digital ICTs are increasingly used to
 1234 authenticate a person's identity by measuring the
 1235 person's physiological traits – such as fingerprints,
 1236 eye retinas and irises, voice patterns, facial patterns,
 1237 hand measurements or DNA sampling – or behav-
 1238 ioral features, such as typing patterns. Since they also
 1239 require the person to be identified to be physically
 1240 present at the point-of-identification, biometric sys-
 1241 tems provide a very reliable way of ensuring that the
 1242 person is who the person claims to be; of course not
 1243 always, and not infallibly – after all Montaigne used
 1244 the extraordinary case of Martin Guerre to challenge
 1245 human attempts ever to reach total certainty – but far

more successfully than any arbitrary label can. It is a
 matter of degree. 1246 1247

All this is not to say that we should embrace bio-
 metrics as an unproblematic panacea. As Alterman
 (2003) has correctly shown, there are many risks and
 limits in the use of such technologies as well. But it is
 significant that digital ICTs, in their transformation
 of the information society into a digital community,
 are partly restoring, partly improving (see the case of
 Martin Guerre) that reliance on personal acquaint-
 ance that characterized relations of trust in any small
 town. By giving away some information, one can
 safeguard one's identity and hence one's informa-
 tional privacy, while taking advantage of interactions
 that are personalized (through preferences derived
 from one's habits and behaviours) and customized
 (through preferences derived from one's expressed
 choices). In the digital community, you are a recog-
 nized individual, whose tastes, inclinations, habits,
 preferences etc. are known to the other agents, who
 can adapt their behaviour accordingly. 1248 1249 1250 1251 1252 1253 1254 1255 1256 1257 1258 1259 1260 1261 1262 1263 1264 1265 1266

As for protecting the privacy of biometric data,
 again, no rosy picture should be painted, but if one
 applies the "Convention of Geneva" test, it seems
 that even the worst enemy could be allowed to
 authenticate someone's identity by measuring her
 fingerprints or his eye retinas. They seem to be per-
 sonal data that is worth sacrificing in favour of the
 extra protection they can offer of one's personal
 identity and private life. 1267 1268 1269 1270 1271 1272 1273 1274 1275

Once a cost/benefit analysis is taken into account,
 it makes sense to rely on authentication systems that
 do not lend themselves so easily to misuse. In the
 digital community, one is one's own information and
 can be (biometrically) recognized as oneself as one
 was in the small village. The case of Martin Guerre is
 there to remind us that mistakes are still possible. But
 their likelihood decreases dramatically the more
 biometric data one is willing to check. On this,
 Penelope can teach us a final lesson. 1276 1277 1278 1279 1280 1281 1282 1283 1284 1285

Conclusion 1286

When Odysseus returns to Ithaca, he is identified four
 times. Argos, his old dog, is not fooled and recognizes
 him despite his disguise as a beggar. Then Eurycleia,
 his wet-nurse, while bathing him, recognizes him by a
 scar on his leg, which he had received from a boar
 when hunting. He then proves to be the only man
 capable of stringing Odysseus' bow. All these are
 biometric tests no Arnaud du Tilh would have pas-
 sed. But then, Penelope is no Bertrande either. She
 does not rely on any "unique identifier" but finally
 tests Odysseus by asking Eurycleia to move the bed in
 1287 1288 1289 1290 1291 1292 1293 1294 1295 1296 1297

1298 their wedding-chamber. Odysseus protests that this is
 1299 impossible: he himself had built the bed around a
 1300 living olive tree, which is now one of its legs. This is a
 1301 crucial piece of information that only Penelope and
 1302 Odysseus ever shared. By naturally relying on it,
 1303 Odysseus restores Penelope's full trust. She recog-
 1304 nizes him as the real Odysseus not because of who he
 1305 is or how he looks, but, ontologically, because of the
 1306 information that they have in common and that
 1307 constitutes both of them as a couple. Through the
 1308 sharing of this piece of information identity is
 1309 restored and the supra-agent is reunited. There is a
 1310 line of continuity between the roots of the olive tree
 1311 and the married couple. For Homer, their bond was
 1312 *homophrosyne* (like-mindedness); to Shakespeare, it
 1313 was the marriage of true minds. To us, it is infor-
 1314 mational privacy that admits no ontological friction.
