Circular Economy in Polyisocyanurate-based Insulation: Lifecycle Cost and Glycolysis Recycling Modelling

Abstract

Purpose: The purpose of this study is to evaluate the economic impact of the integration of Circular Economy (CE) principles into the recycling processes of polyisocyanurate (PIR)-based building thermal insulation.

Design/methodology/approach: The study focuses on the glycolysis recycling of PIR waste and identifies factors influencing the cost-effectiveness of polyol recovery. An agent-based model was designed for product circularity assessment and Lifecycle Cost Analysis (LCCA). The model was applied and evaluated on a polyurethane (PUR)-based PIR building thermal insulation product. Sensitivity analysis was conducted to identify and assess the sources of uncertainty within the model.

Findings: The results identified that the cost of glycolysis agents and the catalyst contributed to 62% of the cost of the polyol recovery process compared to PIR waste. This study highlights the impact of supplementary materials in polyol recovery. Results also highlight how excessive methylene diphenyl diisocyanate (MDI) significantly influences the cost of recycling PIR building thermal insulation.

Originality: This study provides insights into the economic feasibility and material impacts of integrating CE in PIR insulation recycling.

Practical implications: CE of the least recycled materials such as PIR is as an effective alternative to provide a sustainable economic growth and to protect against natural capital depletion.

Keywords: Circular Economy; Remanufacture; Lifecycle Cost; Agent-based modelling; Polyurethane; Thermal Insulation

1. Introduction

Thermal insulation is broadly regarded as one of the most effective measures for enhancing the energy performance of buildings by reducing heat transfer within building envelopes, leading to lower heating and cooling demand and greater overall energy efficiency (Stephan and Athanassiadis, 2017). It offers substantial advantages for both construction firms and building owners by reducing energy use, lowering associated costs, and minimising environmental

1
2
3 impacts, making it a highly favourable option across the sector (Abu-Jdayil *et al.*, 2019). PIR
4 and PUR insulation materials offer valuable utility due to their energy efficiency and potential
5 for recyclability (Prażat *et al.*, 2023; Reinerte *et al.*, 2024). This performance is enhanced by
6 the insulation's long lifecycle, which eliminates the need for regular replacements and reduces
7 construction waste (Nasir *et al.*, 2017). These insulation materials are widely used in
8 residential, commercial, and industrial buildings that require strong thermal performance and
9 adherence to fire-safety standards (Schiavoni *et al.*, 2016). Due to its strong thermal
10 performance and adherence to fire-safety standards, the use of PUR-based PIRs has expanded
11 with increasing adoption of high-performance building envelopes and nearly-zero-energy
12 building requirements (Prażat *et al.*, 2023). The insulation can be applied to roofs, external
13 walls, facades, and cold-storage systems (Lakatos *et al.*, 2023). However, these materials,
14 despite their long use, often end up in landfills, resulting in significant waste generated after
15 demolition or major building maintenance. Handling PIR insulation waste poses technical and
16 environmental challenges due to its thermoset polymer structure, which makes it systematically
17 demanding to be reprocessed (Gahlen *et al.*, 2021). Chemical additives, layered facings, and
18 flame retardants complicate separation and treatment processes (Thiounn and Smith, 2020).
19 During disposal, PIR can generate hazardous decomposition products, and limited recycling
20 infrastructure further restricts large-scale recovery. These factors increase the cost and
21 complexity of managing PIR waste within construction supply chains (Geyer *et al.*, 2017). PIR
22 waste management presents challenges in both high-income, and low- and middle-income
23 countries (LMCs), although for different reasons. High-income countries generate larger
24 volumes of PIR waste due to widespread insulation use driven by rigorous energy-efficiency
25 standards (Mohajerani *et al.*, 2020). In contrary, LMCs typically lack adequate recycling
26 infrastructure, formal waste-collection systems, and regulatory frameworks, which increases
27 reliance on landfilling or informal disposal, which consequently makes PIR waste management
28 to be considered as a global issue that manifests differently across economic contexts (Tian *et*
29 *al.*, 2024). Efforts to manage these insulations include the development of chemical recycling
30 approaches such as glycolysis recycling, which can recover polyols for reutilisation in polymer
31 production (Amran *et al.*, 2021). Moreover, several manufacturers have piloted take-back
32 schemes and recycling programmes to increase material recovery ratios. Policy initiatives in
33 Europe and other countries encourage diversion of insulation waste from landfills through
34 extended producer responsibility, landfill taxes, and more sustainable strategies (European
35 Commission, 2020).

Circular Economy (CE) helps reduce carbon emissions by optimising material production to conserve energy and resources, and by promoting closed-loop lifecycles in waste management (Adelekan and Sharmina, 2024; Amir *et al.*, 2023; Khajuria *et al.*, 2022). In 2002, approximately 376 million kilograms of PUR and PIR insulation foam were incorporated into new products (Zia *et al.*, 2007). Considering the utilisation of insulation materials in the production process by manufacturers and consumption by customers, the concept of 6-R (Redesign, Reduce, Reuse, Repair, Recycle, and Recover) has been brought into consideration to apply the CE concept (Özkan *et al.*, 2025). From a recycling perspective, PUR and PIR insulations can be processed through various recovery methods, including mechanical and chemical recycling approaches (Gu *et al.*, 2021). Chemical recycling processes, such as glycolysis make it possible to recover high-value polyols that can be incorporated back into the production of new insulation products (Lee and Jung, 2022). Kanchanapiya *et al.* (2021) examined the economic feasibility of recycling PUR-based insulation wastes in Thailand using a single-phase glycolysis recycling and found that the regenerated polyol provides substantial financial advantages and performs correspondingly to polyols obtained from virgin material. Numerous studies examined the energy performance, environmental impacts, and lifecycle assessment of incorporating PUR-based PIRs into buildings; however, research addressing the economic lifecycle dimensions of these products within Sustainable Development (SD) and CE frameworks has remained comparatively limited. Gigasari *et al.* (2023) carried out a cradle-to-gate Lifecycle Assessment (LCA) that focused solely on assessing carbon payback times when optimising insulation materials for various building orientations. In an experimental study by Prałat *et al.* (2023), which examined the thermal performance of an innovative PUR-based PIR insulation, the authors did not address cost analysis or the economic implications of their findings. This gap is likely the result of limited emphasis on economic circularity assessments, such as Lifecycle Cost Analysis (LCCA), within existing research, as well as a general lack of specialised expertise in this area among researchers and industry practitioners (Altaf *et al.*, 2024). To view PIR waste as an asset, and to examine the applicability of CE principles for this material/product, this study aims to conduct an LCCA of the material across its value chain. The findings provide meaningful insights to construction companies, recycling firms, and policymakers in the field.

The paper is organised as follows: Section 2 provides a detailed literature review of CE within the context, focusing on thermal insulation and, in particular, PUR and PIR-based insulations. Section 3 provides a succinct outline of the methods used in this research. Section 4 presents the study results and provides the calculated costs associated with the various scenarios in

1
2
3 PIR's end-of-life, followed by a critical discussion, embracing nuanced elements from the
4 results and assessing how they compare with the existing research. The paper is concluded in
5 Section 5.

8 **2. Literature Review**

9 **2.1 Circular Economy**

10
11 As a response to the prevailing linear model of take-make-dispose, the Circular Economy (CE)
12 concept has emerged as an effective approach for supporting sustainable economic growth
13 while reducing pressure on natural resources (Osobajo *et al.*, 2022). This approach seeks to
14 preserve and enhance the value of raw materials, natural resources, and products by retaining
15 them within the system for as long as possible (Merli *et al.*, 2018). The development of a CE
16 relies on the interconnected stages of products, processes, and systems (Jayal *et al.*, 2010). A
17 sustainable outcome cannot be achieved unless product design, production process, supply
18 chain efficiency, management practices, and investment assessments are treated as an
19 integrated system (Singh *et al.*, 2026). To minimise waste generation and support long-term
20 sustainability, the 6R concept principles offer a structured approach for achieving a closed-
21 loop system. These principles, reduce, reuse, recycle, recover, redesign, and remanufacture,
22 guide the handling of materials throughout a product's entire lifecycle, ensuring that resources
23 remain in circulation for as long as possible (Jawahir and Bradley, 2016). The underlying
24 principles give rise to six practical business strategies that support CE implementation:
25 regeneration, sharing, optimisation, looping, virtualisation, and exchange (Macarthur
26 Foundation, 2015; Rashidian *et al.*, 2025). The housing sector, which consumes nearly 40% of
27 all manufactured products during construction, accounts for around 35% of global energy use
28 (Leising *et al.*, 2018; Osobajo *et al.*, 2022). Although the CE concept has been widely examined
29 across various industries and academic fields, its application to the economic, energy
30 efficiency, and environmental dimensions of buildings remains underexplored (Leising *et al.*,
31 2018). Due to its low resource efficiency, the building and construction sector produces close
32 to 100 billion tonnes of construction and demolition waste annually, with roughly a third of
33 this material still being landfilled, which indicates significant challenges for sustainable
34 resource management (Shooshtarian *et al.*, 2024). It is widely recognised that material reuse in
35 construction is difficult, as buildings are typically discarded at the end of their lifespan, as
36 reflected in the United Kingdom's annual production of around 45.8 million tonnes of
37 demolition and construction waste (Akanbi *et al.*, 2018).

2.2 Thermal Insulation and PUR-based PIRs Materials in Buildings

Thermal insulation is widely recognised as an effective means of improving building energy efficiency, offering economic and environmental benefits for both construction firms and building owners (Lakatos *et al.*, 2023). Due to the rapid growth of energy prices and the need for thermal comfort within residential and commercial buildings, thermal insulation products are gaining more attention (Kowalczyk *et al.*, 2023). The deterioration of insulation in older buildings commonly leads to substantial efficiency losses (Chen and Lai, 2025). Traditional insulation materials such as PUR-based insulations, cellulose, mineral wool, cork, glass wool, and polystyrene are widely used in buildings, but they can be costly and, in some cases, pose risks to the environment and human health (Mud Fadhil *et al.*, 2014). Although the use of thermal insulation in construction has increased in recent years, its production and disposal still involve substantial energy consumption and waste generation, largely due to reliance on non-renewable, fossil-based materials (Wang *et al.*, 2018). As an enhanced form of PUR – PIR – offer superior thermal insulation performance (Reinerte *et al.*, 2024). PIRs are among the most applied thermal insulation materials for residential and commercial thermal improvement due to their anti-flammability structure (Lazo *et al.*, 2023). PIRs are generally considered green materials as they are employed to maximise energy efficiency, reduce energy bills and provide thermal comfort within commercial and residential buildings (Gahlen *et al.*, 2021; Lee and Jung, 2022). PIR is also widely used as the insulating core in factory-made sandwich panels, which typically consist of thin metal facings bonded to a light insulating core, and their overall cost structure is strongly influenced by the economic contribution of the core material (Sonnenschein, 2015). In sandwich metal panels, the materials used in the insulation core typically represent a significantly higher cost than the metal facing layers (Mamalis *et al.*, 2008). The focus on the economic lifecycle aspects of these products within the CE perspectives has been, in comparison, substantially limited. Gigasari *et al.* (2023) conducted a cradle-to-gate LCA study to investigate carbon payback time in optimising insulation materials. In an experimental study of thermal characteristics of innovative insulation made of PUR-based PIR by (Prażat *et al.*, 2023), no consideration was given to cost analysis and economic implications. The limited focus on cost analysis in such contexts is generally due to the low interest in conducting economic circularity analysis (Altaf *et al.*, 2024).

2.3 Chemical Composition and Structural Characteristics of PUR and PIR

In the form of foam and CASEs (coatings, adhesives, sealants and elastomers), PURs account for almost 8% of total polymer-based materials produced globally (Kemona and Piotrowska, 2020). As an advanced form of PUR, the variant PIR has shown outstanding thermal insulation

properties (Reinerte *et al.*, 2024). PUR and PIR are both derived from PUR, a plastic material formed through chemical reactions (Kingspan Ltd, 2024). Due to the structural and compositional similarity between these two PUR-derived products, they are named as ‘PIR-PUR foam’ or vice versa (Qian *et al.*, 2022).

2.4 Sources and Generation of PUR-based Waste

The building insulation foam waste is generally generated throughout the manufacturing, construction and demolition phases (WRAP, 2013). In addition, packaging materials associated with PUR-based PIR insulations also contribute to the overall waste stream (Morashti *et al.*, 2022). Although research specifically examining packaging impacts for these products is limited, broader studies indicate that packaging can represent a significant share of product-related material flows and has notable implications for cost and logistics efficiency (Morashti *et al.*, 2022). Most of the generated PUR foam waste is still being transformed into energy as an alternative source of fuel rather than being recycled into a new value-added product (Kanchanapiya *et al.*, 2021). Zia *et al.* (2007) introduced four major practices to recover and recycle PURs, including mechanical recycling, advanced chemical and thermochemical recycling, product recycling, and energy recovery.

At the end of their useful life, clean and undamaged PUR boards have the potential to be reused as second-hand products, maintaining the same characteristics of newly manufactured products (IBU-EPD, 2018; Kingspan Ltd, 2019a; Modesti *et al.*, 2018).

2.5 Recycling Technologies for PUR-based Waste

Glycolysis recycling has been the most marketed depolymerisation method of downgrading, chemically breaking and returning dead products to life by recovering their crucial primary components (Heiran *et al.*, 2021). The main goal of recycling PUR waste via glycolysis is to recover the primary polyol, which can be reused as a raw material for producing new PURs or branded as a fuel (Heiran *et al.*, 2021).

Although mechanical recycling of PUR waste is not as sophisticated as chemical recycling, with lower costs, only 1% of the produced waste is recycled mechanically (Kanchanapiya *et al.*, 2021). The glycolysis recycling of PUR waste provides the opportunity to recover polyols, as well as polyols containing isocyanates (Kanchanapiya *et al.*, 2021). Currently, the glycolysis process is performed through two different methods, single-phase and split-phase, depending on the obtained mixture during the degradation process of polyols (Kanchanapiya *et al.*, 2021). One of the most influential cost categories of chemical recycling of PUR waste is the capital cost of purchasing the required agents and catalysts throughout the process (Kanchanapiya *et*

al., 2021). The potential agents and catalysts convenient for the glycolysis recycling of PUR-based waste are shown in Table .

Table I Agents and catalysts for glycolysis recycling of PUR-based waste (Source: Authors).

Agent Type	Catalyst Type	Reference
Ethylene Glycol (EG)	Organometallic compounds	(Miguel-Fernández <i>et al.</i> , 2022)
Hexamethylene Glycol (HDO)	Sodium Acetate (NaAc)	
Propylene Glycol (PG)	Diethanolamine (DEA)	(Amundarain <i>et al.</i> , 2022)
Diethylene Glycol (DEG)	Potassium Acetate (KAc)	
Dipropylene Glycol (DPG)	Potassium Hydroxide (KOH)	
Pentamethylene Glycol (PDO)	Dimethylaminoethanol (DMAE)	
Glycerine	Sodium Hydroxide (NaOH)	(Gu <i>et al.</i> , 2023)
Trimethylene Glycol	Lithium Octoate	(Kanchanapiya <i>et al.</i> , 2021)
Hexamethylene Glycol (HDO)	Stannous Octoate	
Tetramethylene Glycol (BDO)	Driethylenediamine (DABCO)	
Driethylenediamine (DABCO)	Zinc Acetate (ZnAc ₂)	
Crude Glycerol	-	
Refined Glycerol	-	

A key factor towards recycling PUR-based products through the glycolysis method, is the impurity level of the obtained polyol, as it has a significant contribution towards the polyol mixture ratio in re-producing PUR-based insulations (Miguel-Fernández *et al.*, 2022). Due to its high level of impurities, various studies have been conducted to investigate the utilisation ratio of 10%, 40%, and 70% of the recovered polyol in the polyol mixture to produce new

PUR-based thermal insulations (Kemona and Piotrowska, 2020). Although extensive research examines the chemical mechanisms of glycolysis for PUR-based PIR waste, again far less attention has been given to the economic feasibility of polyol recovery, particularly the influence of glycolysis agents, catalysts, material purity, and reverse logistics requirements on overall recycling costs (Kanchanapiya *et al.*, 2021; Miguel-Fernández *et al.*, 2022; Zia *et al.*, 2007).

2.6 Landfilling and End-of-life Management of PUR-based Waste

Landfilling is still commonly considered as the last disposal destination of municipal solid wastes (Vaverková, 2019). Almost 50% of the generated PUR waste is taken through the landfilling process (Kemona and Piotrowska, 2020). Accordingly, the construction industry owns almost 35% of the landfilled waste throughout the world (DEFRA, 2023). Landfilling of PUR products after their primary lifecycle is the most common waste treatment among others (Miguel-Fernández *et al.*, 2022). It has fewer environmental impacts than incineration due to PUR wastes' long lifecycle, less resource and energy consumption, and greenhouse gas emissions (Deng *et al.*, 2021). It is recommended that PURs should not be landfilled permanently; however, landfilling should be taken as a temporary solution to store the waste before taking it back for the recovery process by considering the most suitable technologies (Kemona and Piotrowska, 2020). Transport distance is a major cost driver in the disposal of construction materials, and existing studies illustrated that long waste-haul distances significantly reduce the economic feasibility of landfill treatment due to fuel, labour, and operational demands (Callao *et al.*, 2021; Kim and Jeong, 2017; Di Maria *et al.*, 2018).

2.7 Product Sustainability Assessment Methods

In line with the principles of LCA, LCCA is used to evaluate the economic sustainability of a product or system by examining capital costs, operational costs, and potential savings across the entire lifecycle (Dwaikat and Ali, 2018). To support clearer decision-making, this method examines the total cost of ownership of the product or system from its initial stage through to end-of-life, covering 5 main phases as: concept and definition, design and development, manufacturing and installation, operation and maintenance, and disposal (Norman, 1990). Significant efforts have been made across multiple sectors, including manufacturing, energy, aerospace, logistics, and construction to develop a structured and detailed LCCA framework since the early twentieth century (Farsi *et al.*, 2020). Data plays a crucial role in identifying the necessary information across a product's lifecycle (Yang *et al.*, 2009). The cost structure is organised into several data input categories, which include linked, unlinked, direct, indirect, variable, fixed, opportunity and sunk costs (Graddy-Reed *et al.*, 2021). A substantial part of

academic and institutional work on LCCA is grounded in the detailed framework developed by the British Standards Institution. The BSI ISO 15686-5 sets out a structured approach for evaluating the lifecycle costs of buildings and construction materials, covering five key whole-life stages: planning, design, construction, operation and maintenance, and end-of-life (BSI ISO15686-5, 2017). Identifying cost drivers across the full lifecycle of an asset is a central component of LCCA, as it helps stakeholders understand cost patterns and potential savings (NATO, 2009). During the manufacturing stage, LCCA depends on factors such as product lifespan, projected sales volume, expected price variability, and the anticipated total costs linked to the product (Kádárová *et al.*, 2015). Moreover, energy consumption in the manufacturing stage is an important contributor to the overall lifecycle cost profile of products, as material choice directly influences processing energy demand (Ivanova *et al.*, 2018; Rivero-Camacho *et al.*, 2023). Transportation distance is one of the dominant cost factors in transporting construction materials, with longer routes significantly increasing fuel demand and overall logistics costs (Daylan and Ciliz, 2016; Kärhä *et al.*, 2024; Zgonc *et al.*, 2019). The installation stage represents a significant element of the overall lifecycle cost of building insulation systems; however, existing research on PUR-based PIR insulation predominantly concentrates on thermal performance and energy efficiency, with comparatively limited analysis on the economic dimension associated with installation (Vasishta *et al.*, 2023; Wiprächtiger *et al.*, 2020).

2.8 Agent-based Modelling

In recent years, Agent-based Modelling (ABM) has received increasing attention in CE research, attracting interest from academics and industry worldwide as a means of analysing and improving the profitability of economic systems. ABM has become a suitable approach for analysing complex bottom-up economic and market modelling (Bert *et al.*, 2015). ABM is widely applied across various sectors, including housing, agriculture, information technology, marketing, manufacturing, and logistics (Luo *et al.*, 2019). ABM focuses on individual units or agents, each with its own characteristics at different stages of the supply chain or lifecycle, and uses their interactions to shape and regulate the behaviour of the overall system or product (Secchi *et al.*, 2024). Agents are understood to operate with autonomy, acting independently based on the information available to them; heterogeneity, reflecting variations in characteristics such as income, preferences, and behaviour; and activity, meaning their actions influence the wider system (Rizzati and Landoni, 2024). They are goal-directed and proactive, establishing objectives beyond routine tasks, and reactive and perceptive, able to recognise and

1
2
3 respond to environmental conditions (Fussone *et al.*, 2025). Agents also operate under bounded
4 rationality, making reasonable decisions despite limited information, as illustrated in
5 emergency-exit choices during a fire (Castle and Crooks, 2006). Furthermore, they are
6 interactive and communicative, exchanging information and detecting inconsistencies, possess
7 mobility that supports dynamic interactions within systems (Drchal *et al.*, 2019), and
8 demonstrate learning and adaptation, adjusting behaviour based on experience to function
9 effectively in changing environments (Li *et al.*, 2019). Within the LCA context, ABM explores
10 how different agent characteristics shape decision-making and, in turn, influence the
11 environmental outcomes of the overall system being analysed (Lan and Yao, 2019). Tong et
12 al. (2023) illustrated that recycling outcomes depend strongly on the waste owner's behavioural
13 tendencies, and their ABM successfully revealed underlying psychological patterns influencing
14 these decisions. Ceschi et al. (2021) applied ABM to a new management policy aimed at
15 nudging recycling behaviour and demonstrated that the model effectively captured how multi-
16 layer agents respond across different variables. Tian et al. (2024) used ABM to design a cross-
17 regional policy design, including a 20% improvement in recycling rates and equivalent
18 emission reductions. In waste-related LCA, where systems involve real-time processes such as
19 collection, sorting, and recycling, ABM supports communication among agents and variables,
20 enabling clearer identification of system interactions and helping reduce emissions, minimise
21 waste generation, and expand recycling opportunities (Kerdlap *et al.*, 2020). ABM is valuable
22 because the overall behaviour of a system emerges from its individual mechanisms, which
23 respond differently depending on their environmental conditions, even when following the
24 same rules, which enables the analysis of these complex and autonomous interactions (Bert *et*
25 *al.*, 2015).

2.9 Research Gaps & Contributions to Knowledge

26 Among various insulation materials, PUR and PIR-based insulations are widely used due to
27 their superior thermal performance and fire resistance (Modesti *et al.*, 2018). However, despite
28 their long lifespan, PIR and PUR insulations often end up in landfills after building demolition
29 or renovation, contributing to significant waste accumulation and environmental concerns
30 (Pralat *et al.*, 2023). Although the CE framework has been recognised, its integration into
31 insulation waste management remains underexplored (Ghisellini *et al.*, 2016). Prior studies
32 have investigated the energy efficiency and thermal performance of building insulation
33 materials; however, there are still gaps in assessing their economic circularity and cost-
34 effectiveness within the CE in this context. Several key limitations have been identified in the
35 literature, which are (i) most studies evaluating building insulation focus on thermal
36

performance and energy efficiency (Gök *et al.*, 2024). However, there is a lack of research integrating LCCA to analyse the economic feasibility of recycling insulation materials (Nyame Uddin *et al.*, 2022). (ii) There are studies on recycling PUR insulation waste, yet specific investigations into PIR-based insulation circularity and cost-effectiveness are limited (Altaf *et al.*, 2024). (iii) Existing research often lacks a complete cost assessment model covering all lifecycle phases, from production to disposal (Nugroho *et al.*, 2022). (iv) Research on glycolysis recycling of PIR insulation remains sparse, particularly regarding the economic impact of additional chemicals such as methylene diphenyl diisocyanate (MDI) and glycolysis agents on polyol recovery costs (Kemono and Piotrowska, 2020). (v) Although ABM is highly capable of handling complex analytical problems, its application has been concentrated mainly in fields such as electrical engineering, robotics and computer science, and building insulation analysis in the literature has been mostly performed within engineering simulation modelling platforms such as DesignBuilder, TRNSYS, AutoDesk, and EnergyPlus (Bastos Porsani *et al.*, 2023; Gök *et al.*, 2024; Pakka *et al.*, 2012; Suresh *et al.*, 2023).

This study addresses these gaps by evaluating the integration of CE principles into the lifecycle cost and recycling processes of PIR-based building thermal insulation. The key contributions are:

1. Performing a full LCCA–economic assessment of PIR insulation within a CE framework, offering insights into cost-effective recycling strategies,
2. Assessing PIR insulation’s circularity through Agent Based Modelling (ABM), which provides a novel methodological contribution to insulation waste management considering non-linearity over lifecycle stages, and
3. Investigating the lifecycle cost implications of glycolysis recycling for PIR waste, identifying the major cost contributors, including catalysts and glycolysis agents.

3. Research Methodology

3.1 Methodological Framework

We have adopted an ABM approach to examine the PIR lifecycle and examine pertinent costs. ABM provides a broad range of advantages, as it allows the comprehensive simulation of agent decision-making, capturing the nuanced behaviours of agents in different circumstances (Wu *et al.*, 2024). Furthermore, ABM consolidates the integration of multiple concepts within one framework, enhancing the model’s flexibility, robustness and comprehensiveness in analysing attributes of complex behaviours such as phase transitions, breaking points and perturbations (Wu *et al.*, 2024).

3.2 Data Collection

This study conducted secondary data collection through an extensive review of literature in scientific databases, governmental guidelines, building thermal insulation manufacturers, approved industry-related institutions, well-recognised online commercial database platforms, and approved industry-related product data sheets. Throughout the data collection process, a wide range of secondary reference materials were collected using suitable field-related keywords to search through the reference materials, including titles, abstracts, and main bodies (Figure 1).

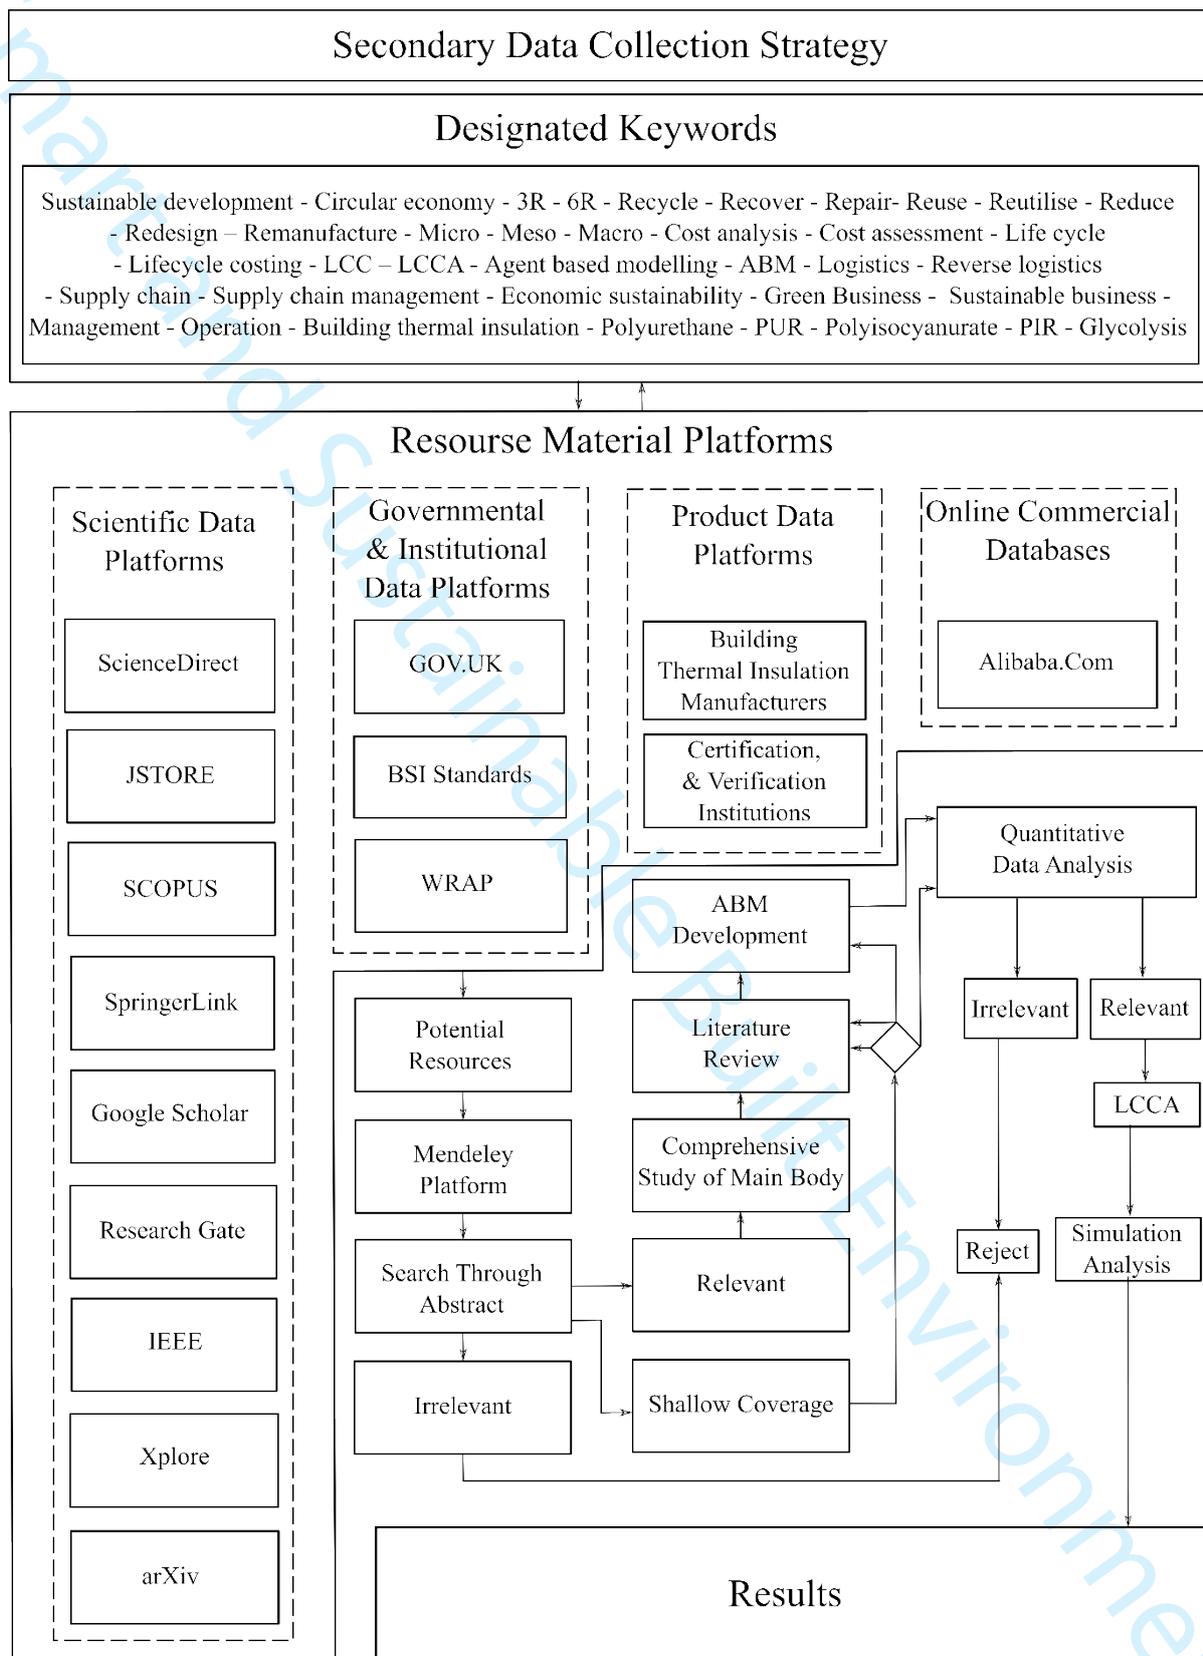

Figure 1. The data collection strategy (Source: Authors).

3.3 Scope and Assumptions

The scope of the developed model for LCCA would be solely to consider the cost drivers and the benefits drivers are considered as input data. The future cost value was used instead of the net present value. A tactical decision was made to eliminate time from the analytical scope of this research, but to keep it only as an illustrative element for the operational interface of the product's lifecycle within the simulation model. The decision was primarily affected by the nature of the collected data for LCCA. The cost of material extraction and transport to the manufacturer was deemed out of scope. Finally, we used the British Pound (£) as the cost unit in our calculations.

It is also assumed that the unit price for the raw material acquisition in the primary lifecycle stays the same to allow the unit prices to be used within the recycling process. Along with this, a future value formula based on the lifespan of the PIR building thermal insulation, which is 75 years, is applied. Due to a lack of reliable data regarding PIR waste scraps cost, as PIR is a PUR-based product and both can be recycled with the same recycling methods, the cost of PUR scraps was calculated for the glycolysis recycling process. Moreover, it is assumed that PUR scraps are mechanically shredded into granules in the recycling plant. The mixture's recovered polyol ratio is assumed as 10%, as per literature data.

3.4 Agent-based Model Development

A novel single-agent model was developed in AnyLogic software (v. 8.9.4) and tailored to conduct LCCA for this study's proposed product, as illustrated in Figure 2.

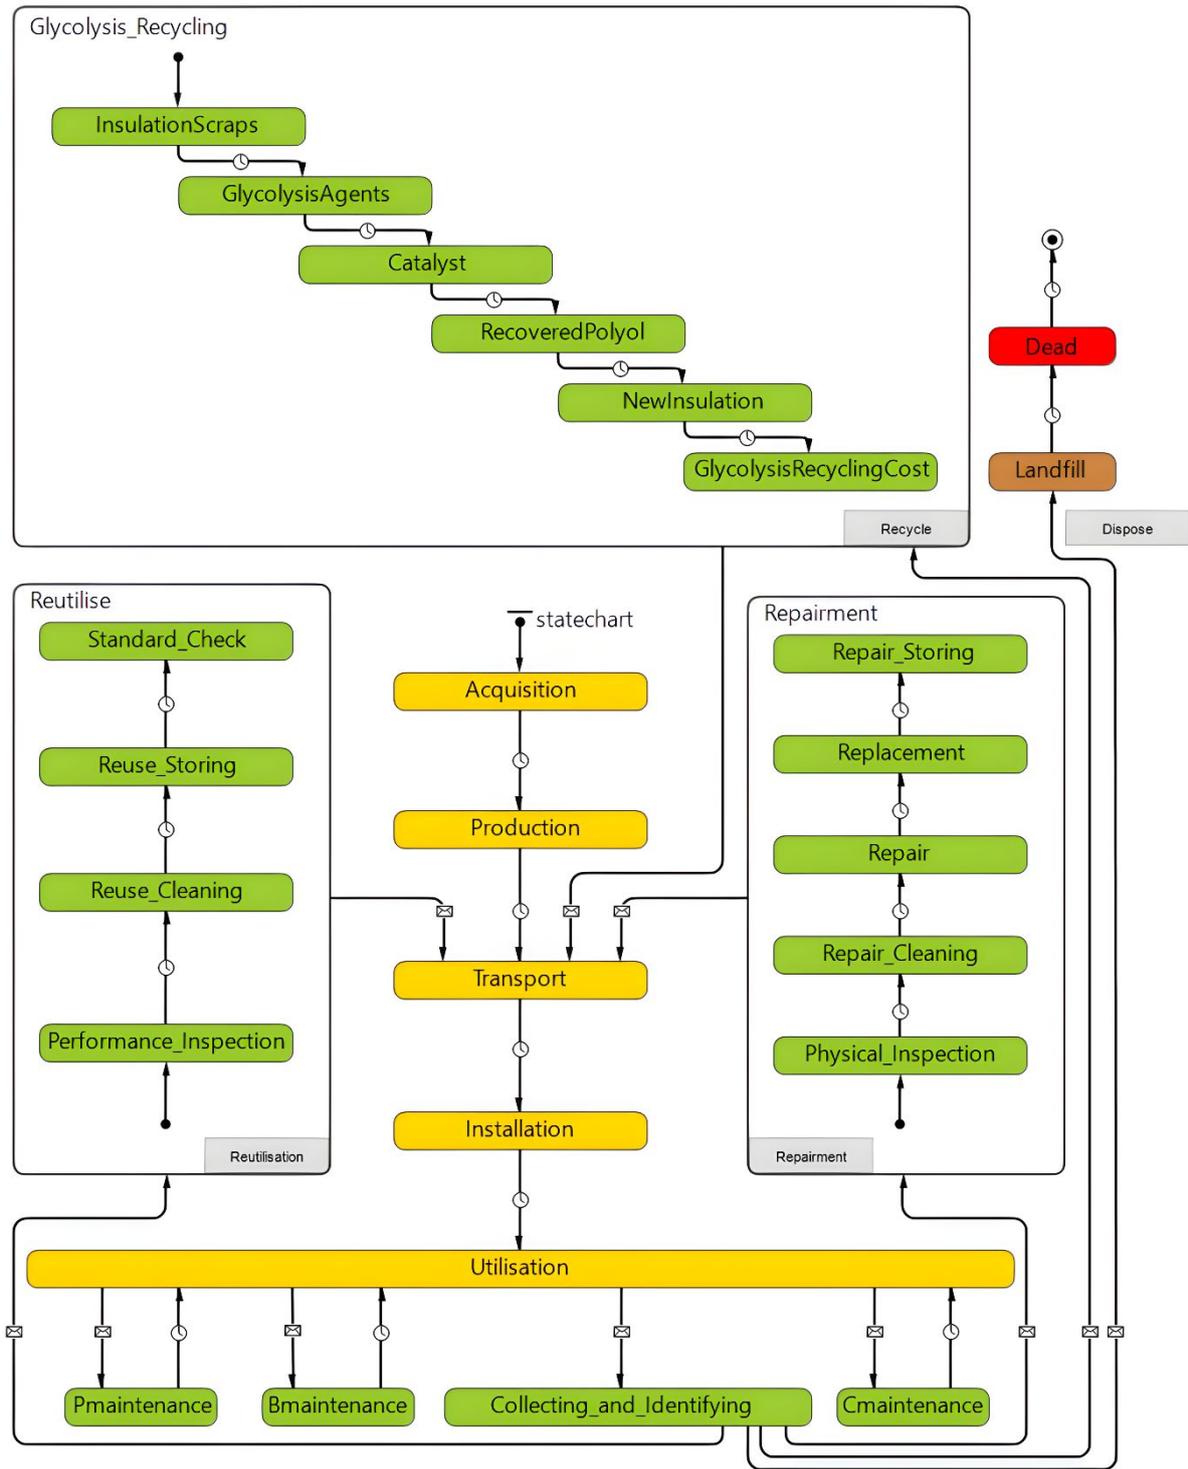

Figure 2. The developed agent-based model (Source: Authors).

The developed ABM has the potential to be tailored to other products with minor adjustments. The model includes the map of the product's entire value chain, from raw materials procurement to green end-of-life and landfill destinations. Figure 3 illustrates the lifecycle of the PUR-based PIR building thermal insulation, and Figure 4 represents the UML state

machine diagram of this model, detailing the applied logic behind the model development in each individual state. The model consists of multiple product lifecycle stages.

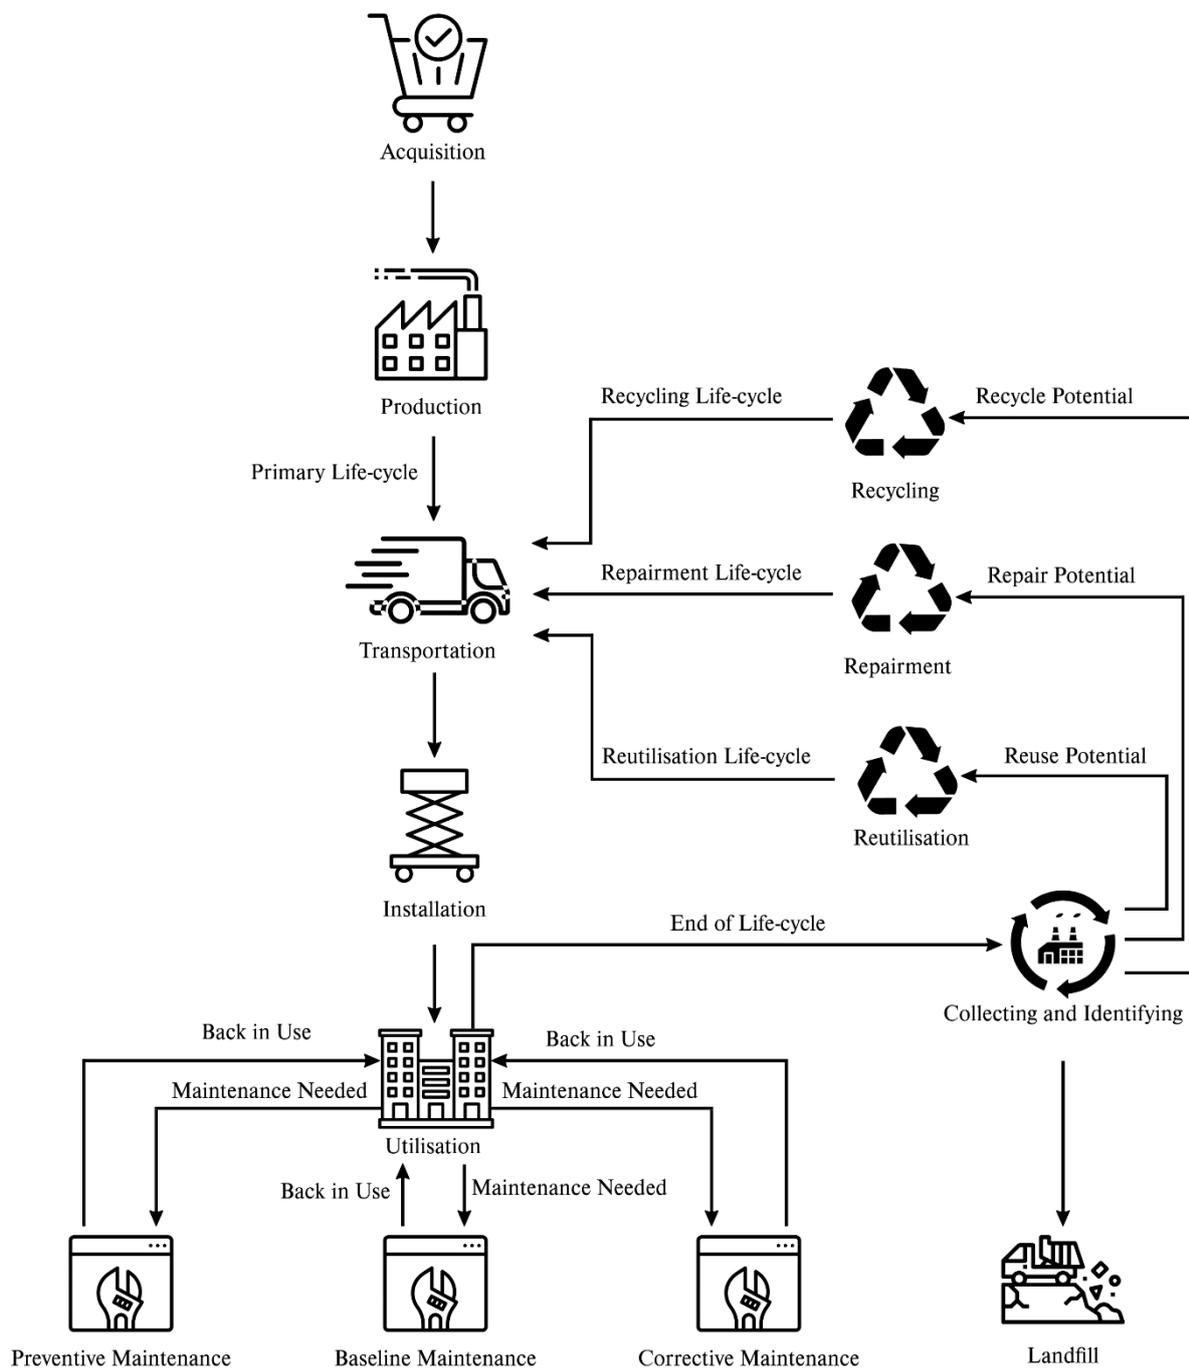

Figure 3. The modelled lifecycle stages of the PUR-based PIR building thermal insulation (Source: Authors).

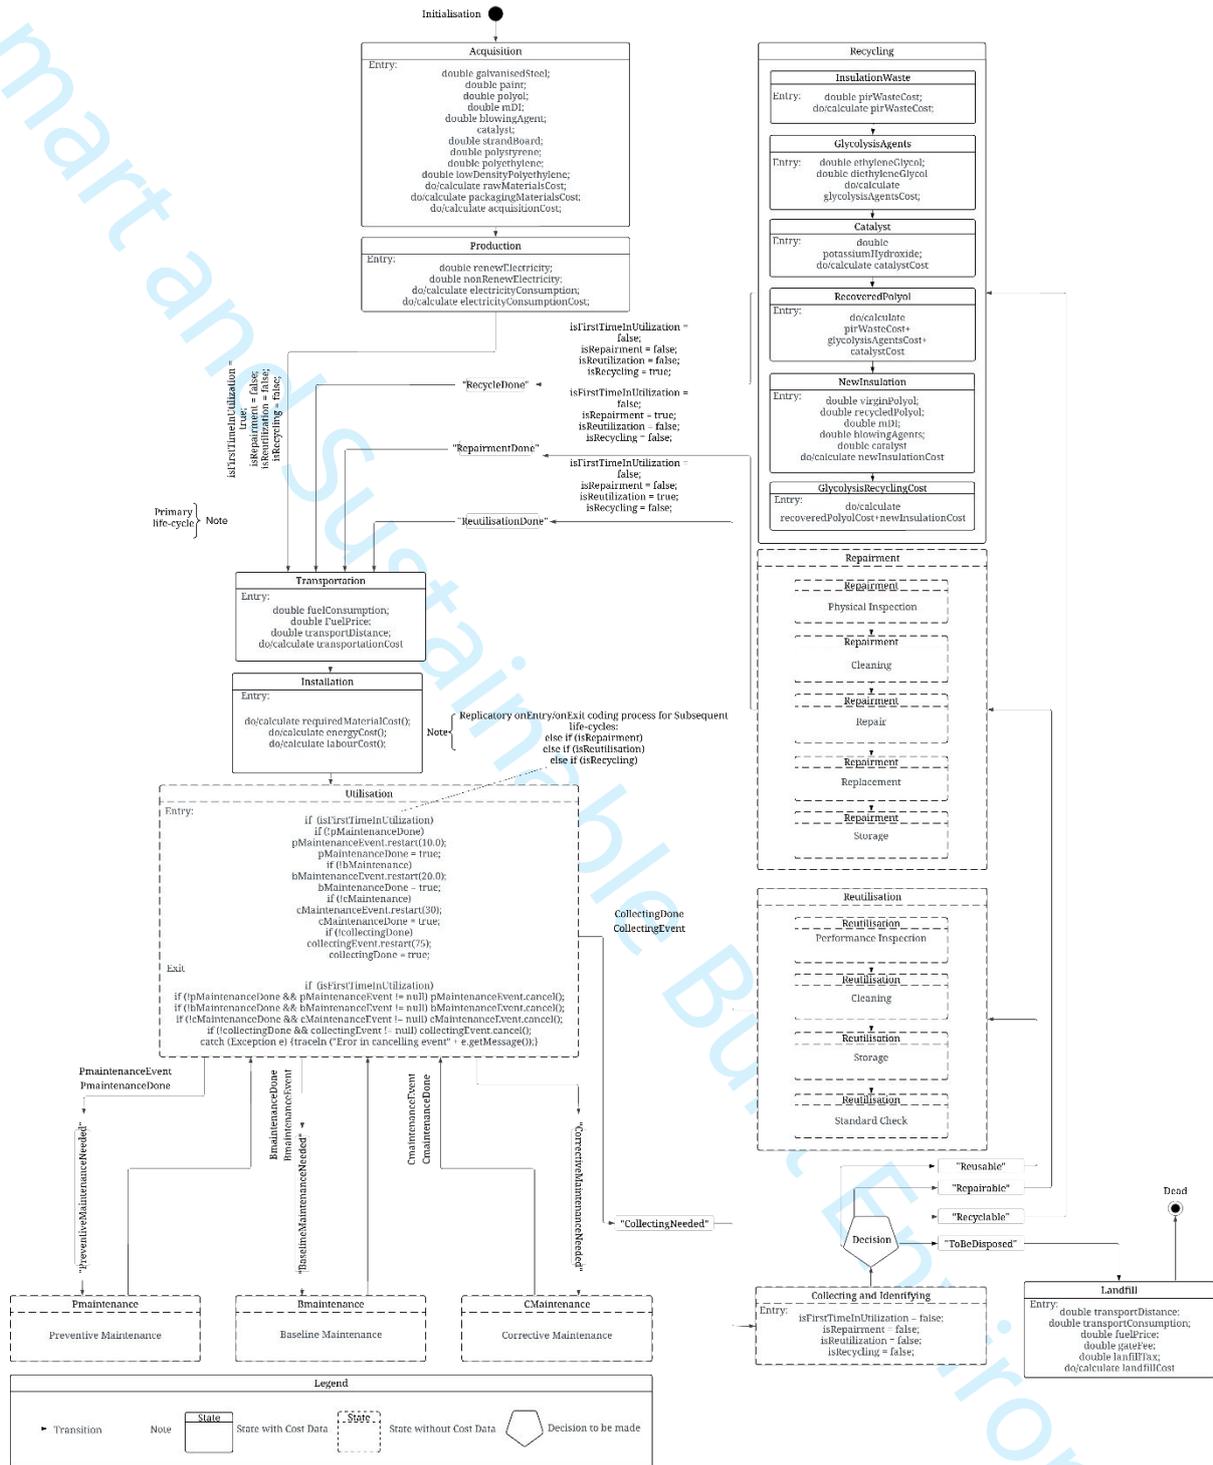

Figure 4. UML state machine diagram of the developed model for PIR building thermal insulation lifecycle (Source: Authors).

The primary lifecycle stage of the model consists of seven stand-alone stages as ‘acquisition’, ‘production’, ‘transport’, ‘installation’, ‘utilisation’, ‘maintenance’, and ‘collecting and identifying’. Once the primary lifecycle ends, four different streams are provided within the model for the product to progress through: ‘after-life reutilisation’, ‘after-life repairment’,

‘recycling’ and ‘landfill’. Three types of transitions are used in the model: transition “Timeout” only for illustration of the product’s lifecycle progression, transition by “message” between each state, and transition by “message” by sending it through a designated button, where a decision needs to be made. Therefore, the developed model represents the entire lifecycle of a product under real-world conditions.

3.5 Lifecycle Cost Analysis Equations

Table II illustrates the LCCA formulas that various scholars employ in previous LCCA research projects. Although LCCA is extensively studied in a diverse and wide range of research projects, LCCA equations vary regarding the utilised symbols and equation components. But all the equations are performed in the same way and provide the same results (Altaf *et al.*, 2024; Brealey *et al.*, 2011; Farsi *et al.*, 2020; Shankar Kshirsagar *et al.*, 2010; Shibata *et al.*, 2023; Zhang *et al.*, 2018).

Table II. Proposed Cost Model – LCCA formulations (Source: Authors).

LCCA formulations
$C_R = T_M \times M_P$ <p>Where, C_R = Composition Ratio; T_M = Total Mass; M_P = Mass Percentage</p>
$LCC = C_A + C_P + C_T + C_I + C$ (Each End-of-life Scenarios = C_{REC} , C_L) <p>where, LCC = Lifecycle Cost; C_A = costs of raw materials acquisitions; C_P = production costs; C_T = transportation costs; C_I = installation costs; C_{REC} = recycling costs; C_L = landfill costs.</p>
$C_A = C_{GE} + C_{PA} + C_{PO} + C_{MDI} + C_{BA} + C_C + C_{SB} + C_{PS} + C_{PF} + C_{LDP}$ <p>where, C_{GE} = cost of galvanised steel coatings; C_{PA} = cost of coating paint; C_{PO} = cost of virgin polyol; C_{MDI} = cost of methylene diphenyl diisocyanate; C_{BA} = cost of blowing agent; C_C = cost of catalyst; C_{SB} = cost of strand board for packaging; C_{PS} = cost of polystyrene for packaging; C_{PF} = cost of polyethylene film for packaging; C_{LDP} = cost of low-density polyethylene film for packaging.</p>
$C_P = C_{RE} + C_{NRE}$ <p>where, C_{RE} = cost of renewable electricity; C_{NRE} = cost of non-renewable electricity.</p>
$C_T = ((T_D * F_C) / 100) * F_P$ <p>where, T_D = transport distance; F_C = fuel consumption per 100/Km; F_P = fuel price.</p>
$C_I = C_{WBC} + C_E + C_{LAB}$ <p>where, C_{WBC} = cost of sealant; C_E = electricity cost during installation; C_{LAB} = labour costs.</p>

$$C_{REC} = C_{PIRW} + C_{EG} + C_{DG} + C_{PH} + C_P + C_{RP} + C_{MDI} + C_{BA} + C_{CAT}$$

where, C_{PIRW} = cost of PIR waste; C_{EG} = cost of ethylene glycol; C_{DG} = cost of diethylene glycol; C_{PH} = cost of potassium hydroxide; C_P = cost of virgin polyol; C_{RP} = cost of recycled polyol; C_{MDI} = cost of methylene diphenyl diisocyanate; C_{BA} = cost of blowing agent; C_{CAT} = cost of catalyst.

$$C_L = C_{TLS} + C_{GF} + C_{LT}$$

where, C_{TLS} = transport to landfill site; C_{GF} = cost of landfill gate fee /tonne/Kg; C_{LT} = cost of landfill tax /tonne/Kg.

$$FV = C_E * (1 + R)^T$$

where, FV = future value of each cost element; C_E = cost element; R = inflation rate; T = product's lifecycle period.

3.6 Secondary Data

Following a comprehensive review of various types of Environmental Product Declaration (EPD) documents for different types of building thermal insulations, it was observed that EPD documents are produced in compliance with ISO 14025, TS/14027, 1440, ISO 21930, and EN 15804 standards, and they provide generalised data about a single product or a class of products within a specific sector or industry (EPDIAB, 2024; Gibson, 2022; Kingspan Ltd, 2019a, 2023). The provided data by the EPD was cross-examined with product datasheets (Kingspan Ltd, 2023), and then the closest product specification for 1 (m²) was selected, as presented in Table .

Table III. PIR insulated metal wall panel thermal insulation (Source: Authors); data extracted from (Kingspan Ltd, 2019a). *Click or tap here to enter text.*

Polyisocyanurate (PIR) Insulated Metal Wall Panel		
Property	Value	Unit
Length (m)	12	m
Width (m)	1	m
Thickness (Core 140)	152.4	mm
Weight	13.5	Kg
R-Value	8.44	(m ² K)/W
U-Factor	0.11	W/(m ² K)
RSL	75	Year

In the first stage, the product composition data were collected to identify the required raw materials in the product's production process (Table IV).

Table IIV. Product Composition Data from EPD (Source: Authors), data sourced from (Kingspan Ltd, 2019a).

Product Composition (EPD)		
Material	Amount (Kg/M²)	Percentage of Total Mass (%)
Galvanised Steel	745.3	64.60 %
Polyisocyanurate	245	21.23 %
Pentane	16	1.39 %
Proprietary Chemicals	147.5	12.78 %
Product Total	1153.8	100%

After collection and examination of the data, the collected values were converted to the product specifications in the datasheet, considering the weight of the product and the composition percentages, using the proportionality formula provided in Table II.

This proportionality calculation was followed with respect to the product's composition provided within the EPD datasheet and has been followed throughout the LCCA for each lifecycle stage section to tailor the collected data based on the chosen product's specifications (Table V).

Table V. Converted ratios for product compositions, unconverted (Source: Authors), data sourced from (Kingspan Ltd, 2019a).

Converted Product Composition		
Material	Amount (Kg/M²)	Percentage of Total Mass (%)
Steel	8.721	64.60%
Polyisocyanurate	2.862	21.20%
Pentane	0.189	1.40%
Proprietary Chemicals	1.728	12.80%
Product Total	13.5	100%

The same procedure was followed to calculate the material compositions for the product's packaging, as shown in Table VI.

Table VI. Product packaging compositions (Source: Authors), data sourced from (Kingspan Ltd, 2019b).

Packaging Composition Data From EPD		
Material	Amount (Kg)	Percentage of Total Mass (%)
Oriented Strand Board	61.9	0.3518
Polystyrene	112	0.6365
Polyethylene Film	2	0.0114
Linear Low-Density Polyethylene	0.058	0.0003
Packaging Total	175.958	100%
Converted Packaging Composition Data Based on EPD		
Material	Amount (Kg)	Percentage of Total Mass (%)
Oriented Strand Board	4.7491	35.1788
Polystyrene	8.5930	63.6516
Polyethylene Film	0.1534	1.1366
Linear Low-Density Polyethylene	0.0044	0.0330
Packaging Total	13.5	100%

Once the data collection for the composition part was finished, the data regarding the manufacturing stage of the product was collected based on the same methodology which was described in previous stages. To obtain the energy consumption ratios for the product, the ratio of the product to the provided data in EPD was used. The collected data and converted rates are demonstrated in Table VII.

Table VII. Product manufacturing data (Source: Authors).

Manufacturing Data From EPD			
Element	Amount	Cost	Reference

Renewable primary energy consumption, excluding the renewable primary energy resources used as raw materials - Electricity (MJ)	3,490	*	(Kingspan Ltd, 2019a)
Non-renewable primary energy consumption excluding non-renewable primary energy resources used as raw materials - Electricity (MJ)	70,500	*	
Converted Manufacturing Data Based on EPD			
Element	Amount	Cost	Reference
Renewable primary energy consumption, excluding the renewable primary energy resources used as raw materials - Electricity (MJ)	40.83	*	*
Non-renewable primary energy consumption excluding non-renewable primary energy resources used as raw materials - Electricity (MJ)	824.88	*	*
MJ to kWh Conversion Factor	0.278	*	(Department for Energy Security & Net Zero, 2023a)
Electricity Tariff	*	0.19	(Department for Energy Security & Net Zero, 2023b)
Product Conversion Ratio	0.012	*	*

Similarly, the same process was followed to collect the required data for transporting the product to the development site, which is illustrated in Table VIII.

Table VIII. Product transportation data.

Transportation Data From EPD

Name	Truck	Unit	Reference
Fuel Type	Diesel	*	(Kingspan Ltd, 2019a)
Litres of Fuel Consumption	39.0625	100 Km	
Vehicle Type	Heavy Duty Diesel	*	
Transport Distance	554	Km	
Weight of Products Transported	1153	Kg/100m ²	
Converted Transportation Data Based on EPD			
Name	Truck	Unit	Reference
Fuel Type	Diesel	*	(Kingspan Ltd, 2019a)
Litres of Fuel Consumption	39.0625	100 Km	
Vehicle Type	Heavy Duty Diesel	*	
Transport Distance	554	Km	
Weight of Transported Product	27	Kg/m ²	
Fuel Price	1.6	(£/L)	

The data for the product lifecycle installation phase was collected and converted, applying the same method applied in previous sections. The data for this stage is illustrated in Table IX.

Table IVIII. Product installation data.

Installation Data From EPD			
Name	Quantity	Unit	Reference
White butyl caulk	15.3	Kg/100m ²	(Kingspan Ltd, 2019a)
Steel			
Electricity	37.7	kWh/100m ²	
Converted Installation Data Based on EPD			
Name	Quantity	Unit	Reference

White butyl caulk Steel	0.3583	Kg/m ²	(Kingspan Ltd, 2019a)
Electricity	0.8828	kWh/m ²	
Labour (2 people)	12	4.5 €/m ²	(Nyers <i>et al.</i> , 2015)

The data regarding the landfill stage of the product are presented in Table X.

Table IX. Product landfill data.

Landfill			
Name	Parameters	Unit	Reference
Transport	Distance (Km)	50	(Crístiu <i>et al.</i> , 2024)
	Fuel Price (1.56€/Km)	€69.9	(Department for Energy Security and Net Zero - GOV.UK, 2023)
	Weight of Waste (Kg)	4.779	(Kingspan Ltd, 2019a)
Landfill	Landfill Gate Fee	75(€/tonne)	(WRAP, 2023)
	Landfill Tax (€/tonne)	€102.00	(GOV.UK, 2023)

Landfill tax and landfill gate fee are not covered in EPD documents. Therefore, the official and approved rates are provided by (GOV.UK, 2023) and WRAP data were used instead. The distance from the collection and identification to the landfill site was collected from (Crístiu *et al.*, 2024) paper as 50km as an assumption.

The cost of virgin raw material acquisition to produce PIR building thermal insulation's primary lifecycle and glycolysis recycling was collected on the Alibaba E-Commerce platform (\$/tonne), then converted to (\$/Kg), which are detailed in Table XI.

Table X. Raw material and Waste acquisition costs

Material Acquisition Cost		
Material Components	Price (\$/Kg)	Reference
Galvanised Steel Internal Face (0.75mm)	\$0.49	(Shandong Guogang Steel Group Co Ltd, 2023)
Galvanised Steel External Face (1mm)	\$0.49	
RAL 9016 - Traffic White Paint (0.1mm)	\$2.50	(Chengdu Hsinda Polymer Materials Co Ltd, 2023)
Polyol	\$2.50	(Zhongshan BASD Chemical Technology Co Ltd, 2024)
MDI	\$2.60	(Anhui Sufine Chemical Co Ltd, 2024a)
Blowing Agent: Pentane	\$3.00	(Xiamen Juda Chemical & Equipment Co Ltd, 2023)
Additives: (Chlorinated - Phosphorus Based)	\$2.18	(Jinan Juheng Chemical Co Ltd, 2023.)
Oriented Strand Board	\$12.00	(Linyi Yachen Wood Industry Co Ltd, 2023)
Polystyrene	\$1.00	(Shanghai Allwin Advanced Material Co Ltd, 2023)
Polyethylene Film	\$1.50	(Henan Talent Trading Co Ltd, 2023)
Linear Low-Density Polyethylene	\$12.80	(Shenzhen Shenhongji Packaging Material Co Ltd, 2023)
Polyisocyanurate Foam Waste Excluding the Coatings	\$1.91	(FMCGTRADE, 2024)
Ethylene Glycol	\$0.95	(Anhui Sufine Chemical Co Ltd, 2024b)
Diethylene Glycol	\$0.80	(Shandong Arctic Chemical Co Ltd, 2024)
Potassium Hydroxide - KOH	\$1.20	(Shandong Near Chemical Co Ltd, 2024)

The glycolysis agents' ratios (EG, DEG) and catalyst ratio (KOH) were used as 60/40% of the weight of the utilised waste for glycolysis agents, respectively, and 0.5% for the catalyst from which they were collected (Gu *et al.*, 2021). Furthermore, the ratio of the recovered polyol to the glycolysis polyol mixture from which it was collected was taken as 10/90% (Miguel-Fernández *et al.*, 2022).

4. Results and Discussion

Table XII illustrates the total lifecycle cost, including the cost of each individual lifecycle stage of the PIR building thermal insulation, based on the two defined after-life methodologies of glycolysis recycling and product landfill.

Table XII. PIR building thermal insulation lifecycle cost.

Product Lifecycle Cost Summary		
Lifecycle Stage	Without Future Cost Value (£)	With Future Cost Value (£)
Raw Material Acquisition	£13.60	*
Packaging Raw Material Acquisition	£21.50	*
Manufacturing	£46.41	*
Transportation	£346.2	*
Installation	£94.92	*
Glycolysis Polyol Recovery Material Acquisition	£6.18	£135.10
Glycolysis New Thermal Insulation Material Acquisition	£9.26	£203.03
Landfill Costs	£31.3	£684.47
End-of-Life Destinations		
Glycolysis Recycling Method	£538.10	£860.79
Landfill Method	£553.98	£1,207.14

The findings of this study provide a unique perspective on the economic circularity of PIR building thermal insulation, particularly through LCCA. The existing research on insulation materials has focused on thermal performance and energy efficiency, with studies relying on engineering simulations (Gök *et al.*, 2024).

1
2
3 Considering the specifications of the PIR building thermal insulation, which is 12m², and its
4 weight, which was obtained as 13.5Kg, the total cost of raw materials acquisition for the
5 product was calculated as £13.60. MDI contributed the most to the total cost of the product,
6 with £4.89 for 2.4Kg, which is slightly higher than the cumulative cost of galvanised steel and
7 paint, with £4.08. Also, the cost of the external galvanised steel layer (1mm thickness) was
8 £1.80, which was higher than the inner layer's cost of £1.35 (0.75mm thickness). This was due
9 to the outer layer's thickness and, subsequently, more weight. The cost of polyol, with 1.5Kg
10 weight, was obtained as £2.92, and it was followed by catalyst with £1.15 for 0.7kg weight.
11 The results indicate that the cost of the raw materials used for the insulation product's core
12 material has contributed 70% of the cost of the PIR insulation. In comparison, the cost of metal
13 facings with paint contributed only 30% of the cost of raw material acquisitions in this section.
14 These results align with (Kirugulige *et al.*, 2005; Mamalis *et al.*, 2008), who observed that in
15 sandwich panels, the insulation core contributes the largest share of material cost compared
16 with metal facings. This highlights the need to select core materials that balance performance
17 with cost, and supports the CE principle of sustainable design, which seeks to maintain product
18 efficiency across all lifecycle stages and enable reuse, repair, and recycling (Mamalis *et al.*,
19 2008).
20

21
22 The results discovered that the materials acquisition cost for PIR building thermal insulation
23 packaging is 61% of the cost of the materials acquisition stage. The cost of materials acquisition
24 for the product's packaging was calculated as £21.50, slightly lower than twice the amount of
25 raw materials acquired for the product itself. The required packaging weight for the product
26 was obtained as 13.5Kg. Polystyrene had the most contribution to the weight of the packaging
27 with 8.59Kg. However, polystyrene had the lowest contribution to the total cost of packaging,
28 with £0.79. In comparison, the lower-density polyethylene film cost was calculated as £10.08,
29 the highest among the other contributors but with a minimal weight of 0.004Kg. Strand boards
30 contributed to the second cost of the packaging with £9.45 for 4.75 kg of weight. The findings
31 are consistent with research showing that packaging can be a major cost driver within logistics
32 and handling processes (Morashti *et al.*, 2022). The high packaging costs identified in this
33 simulation highlight the need for strategic procurement decisions for PUR-based PIRs, which
34 are lightweight, high-volume, and often require protective facings. This also aligns with CE
35 principles of sustainable product design, where packaging choices should minimise cost and
36 material use across all lifecycle stages while supporting efficient transport, storage, and waste
37 management (García-Arca *et al.*, 2017).

1
2
3 The electricity consumption cost during manufacturing was calculated as £46.4 using the MJ
4 to kWh conversion factor. The non-renewable electricity consumption was calculated as £44.2,
5 which was significantly higher than the cost of renewable electricity consumption, with only
6 £2.2. The electricity consumption results support earlier findings that manufacturing energy
7 represents a notable indirect cost in PUR-based insulation production (Rivero-Camacho *et al.*,
8 2023). The small variance between raw material and electricity costs suggests that energy
9 demand is closely tied to material selection, as different formulations require distinct reaction
10 times and temperatures, sometimes necessitating additional additives or catalysts to maintain
11 efficient processing.
12

13
14 The cost of transportation to the building development site was calculated at £346.2. The major
15 contributor to the cost of transportation was identified as a *total* transport distance of 554km,
16 significantly affecting the cost of transport. Focusing on the transportation cost, in the EPD
17 document, the weight of the cargo has already been applied to the truck's fuel consumption
18 ratio per 100 km, which is 39.06 (L/100km). The transportation align with studies showing that
19 transport distance is the primary driver of logistics cost for construction materials (Zgonc *et*
20 *al.*, 2019). In this analysis, the 554 Km delivery route accounted for the highest cost among the
21 primary lifecycle stages, reflecting the strong sensitivity of transport cost to distance and fuel
22 consumption. This is consistent with evidence that lightweight but high-volume PUR-based
23 PIRs occupy significant cargo space, which reduces loading efficiency and increases the need
24 for additional transport trips, ultimately raising overall cost (Kärhä *et al.*, 2024). The reliance
25 of transport operations on fossil fuels further amplifies this cost sensitivity (Daylan and Ciliz,
26 2016). Therefore, results highlight the need for further investigation into transportation
27 optimisation for PUR-based PIR insulation products.
28

29
30 The labour cost for two people significantly contributed to the installation cost of £91.80. The
31 cost of required butyl caulk was calculated as £2.95, which was higher than the cost of
32 electricity consumption at £0.17. Thus, the cost of PIR building thermal insulation was
33 obtained as £94.92. This stage accounted for a significant proportion of the primary lifecycle
34 cost, reflecting how installation expenses can vary with labour rates, equipment requirements
35 and project complexity (Vasishta *et al.*, 2023; Wiprächtiger *et al.*, 2020). This is directly
36 connected to the CE principle of optimising processes, which emphasises reducing resource
37 utilisation, labour intensity, and operational inefficiencies throughout the entire lifecycle of the
38 insulation. However, published research on PUR-based PIR insulation focuses largely on
39 performance and energy outcomes, with limited attention to detailed LCCA of the installation
40 process.

1
2
3 In terms of glycolysis polyol recovery, the total weight of needed materials for this stage was
4 8.8Kg. PIR waste had the maximum weight of 4.78Kg, followed by EG with 2.87Kg, DEG
5 with 1.15Kg, and KOH with 0.01Kg. The total cost of polyol recovery through the glycolysis
6 process is £6.18, and by considering the future value of each material over 75 years, the
7 glycolysis recycling's polyol recovery process was calculated as £135.10. PIR waste
8 contributed the most to the polyol recovery cost by £2.43 and £53.12. Catalyst had the second
9 cost contribution, which was followed by the cost of EG and DEG, respectively. The cost of
10 the catalyst was calculated as £1.52 before and £33.35 after application of the future cost value,
11 which was slightly higher than the cost of EG and DEG, with £1.21 and £1.02 without the
12 future cost value, and £26.40 and £22.23 after application of the future cost value, respectively.
13 However, based on the recovered polyol's 10% ratio within the polyol mixture, this cost
14 element needed to be deducted from the mixture ratio cost to calculate the required virgin
15 polyol for a new product. By adding the weight of required materials for the new PIR
16 production process to the weight of used materials in the recovery process, the total weight
17 required for the entire recycling process was calculated as 13.6Kg. Consequently, the cost of
18 required materials to produce a new building thermal insulation (excluding the polyol recovery
19 stage) was calculated using the same cost data for the raw material acquisition stage as £9.26
20 without using future cost value, and £203.03 with applying the future cost value. Therefore,
21 the total cost of glycolysis recycling without the future value was obtained as £15.44,
22 considering the future value of £338.13. The glycolysis results indicate that material
23 composition strongly shapes recycling costs. MDI remains the main cost driver, and higher
24 ratios increase raw material expenditure. MDI contributes 32% due to its extra ratio in the
25 mixture compared with other materials, which is 2.4Kg. MDI is a key component broadly used
26 for chemical reactions in producing PUR-based products, and its ratio should be considered
27 during the production process, as it significantly affects the cost of material procurement. A
28 higher proportion of MDI component to achieve enhanced product capabilities and
29 characteristics in PIR insulations has an impact potential on the initial raw materials acquisition
30 costs of PIR products and, at the same time, transforms the parent variance PUR from a low-
31 cost to an expensive product with consuming more virgin materials. The cost of EG, DEG, and
32 KOH contributed to 20%, 17%, and 25% of the polyol recovery process, respectively, showing
33 their pivotal role in affecting glycolysis recycling's economic feasibility, marked by the
34 allocation of 62% of this process's cost to themselves. It should also be considered that the
35 cumulative weight of these entities, 4.03Kg, is slightly lighter than the weight of the utilised
36 PIR waste, 4.78Kg. This highlights that an increase in the volume of their utilisation ratio

60

would be extremely cost-effective. But more importantly, an excessive amount of PIR waste - glycolysis agents, and catalysts - would result in impurity ratios within the obtained polyol product, which would ultimately affect the utilisation ratio of the recycled polyol within the polyol mixture to produce new insulations or additional treatments should be carried out to improve the impurity level of the obtained polyol (Kemono and Piotrowska, 2020; Miguel-Fernández *et al.*, 2022). It should be noted that as the glycolysis process is dependent on temperature; a temperature below 180°C to reduce energy consumption costs would result in low catalyst activity, and a temperature above 220°C to accelerate the chemical reaction results in undesired reactions, both of which would eventually lead to significant cost increases. Therefore, recycling profitability is further constrained by reverse logistics costs, particularly when waste purity is low, and by the substantial cost share of glycolysis agents and catalysts, which are considered to be major determinants of feasibility (Kanchanapiya *et al.*, 2021; Zia *et al.*, 2007).

The cost of transport to the landfill site was calculated at £31.03. However, by applying the future cost value over 75 years, the cost significantly increased to £684.47. In the simulation analysis, the glycolysis recycling cost was obtained as £538.10 and £860.79, which was cheaper than the landfill by £553.98 and £1,207.14, respectively. These results indicate that transportation has contributed to 97% of the landfill's total cost, highlighting an additional barrier: the transportation cost of waste to the landfill site due to the distance factor. These findings align with Kanchanapiya *et al.* (2021), who reported that transport costs for PUR-based PIR waste are considerably high, making distance a critical barrier to landfill feasibility. Transport costs between collection and disposal facilities directly reduce economic viability, particularly for lightweight, high-volume materials such as PUR-based PIR insulations. Longer haul distances require additional fuel, labour and equipment, and adds both economic and ecological burdens. The sharp rise in transport costs when future values are applied reflects expected long-term fuel price fluctuations and inflation, indicating the value of lifecycle-based budgeting tools such as future and net present value for long-term circularity assessment.

4.1. Model Validation: OAT Sensitivity Analysis

In the first step of the sensitivity analysis, the glycolysis recycling process was identified as the key area likely to significantly affect the total lifecycle cost of PIR insulation, due to its multiple cost components. The entire glycolysis recycling process of PIR insulation consists of two major states: polyol recovery and production of new PIR insulation, along with the applied future cost value for the lifespan of the PIR insulation over 75 years. Three scenarios of reducing the cost of each component by 10, 30 and 50% were developed to explore the range

1
2
3 of possible output variations. To check the robustness of the model, the cost of PIR foam waste
4 procurement, the cost of MDI procurement, and the cost of virgin polyol procurement were
5 selected as the three input variables. The results of input variable manipulation were observed
6 in the cost of glycolysis recycling and the total lifecycle cost of the product. The logic of
7 defining three different inputs at a time and two outputs was to check the differentiation within
8 both the local and global ranges of the input variables to outputs, along with replication
9 processes with other inputs to increase the confidence of the model to conduct simulation
10 analysis. The results of input cost manipulations to the outputs per percentage and by cost
11 reductions are detailed in Figure 5., respectively.

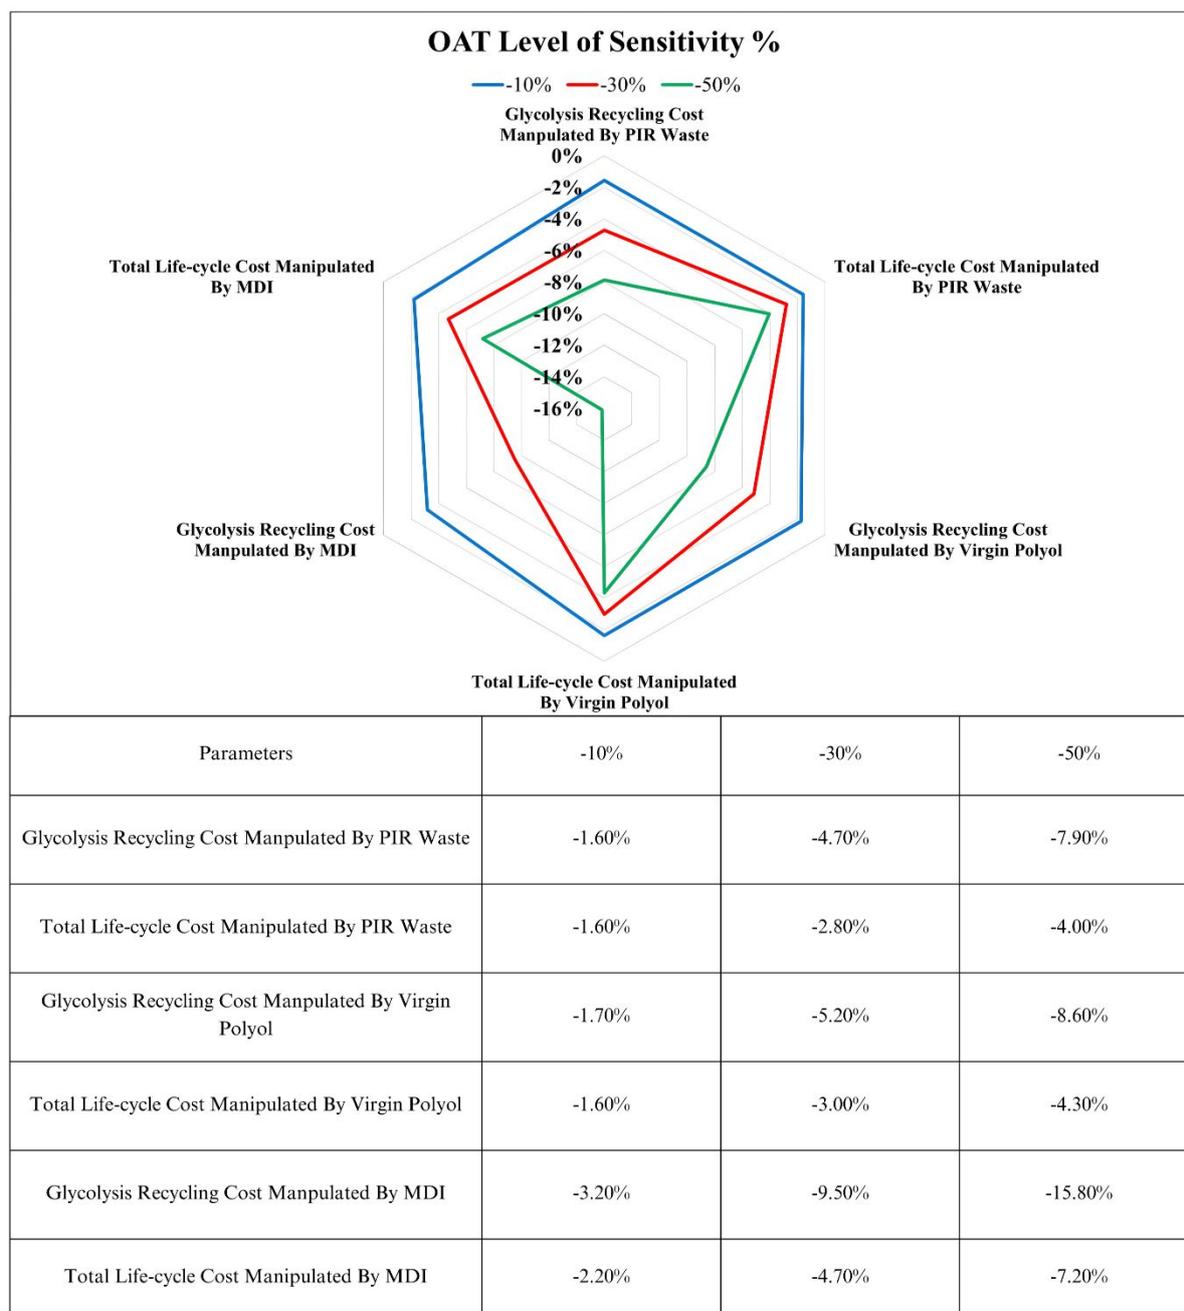

Figure 5. OAT Sensitivity Analysis Scenarios by percentage variations (Source: Authors).

Accordingly, MDI had the highest simulation model’s input manipulation potential among the others by -3.2, -9.5, and -15.8% by each of the reduction scenarios. Moreover, all the selected inputs have contributed to proportional and predicted changes in the selected outputs, indicating that the developed model is proportionally sensitive to input changes.

5. Conclusions

This study presents a comprehensive economic circularity assessment of PIR-based building thermal insulation, highlighting the cost implications across its lifecycle, from raw material acquisition to end-of-life disposal. The results highlighted the significant role of MDI and glycolysis agents in the economic feasibility of PIR recycling, with MDI contributing 32% of glycolysis costs and glycolysis agents accounting for 62% of polyol recovery expenses. Additionally, packaging costs were identified as a significant financial burden, which demonstrates the need for optimised supply chain strategies. The results indicated that using ineffective and undesirable ratios of raw materials leads to a significant direct and indirect cost increase, higher energy consumption costs, and inefficiency throughout the process. Moreover, the cost of packaging products was higher than the cost of raw materials for the main product, directly and indirectly impacting the product's lifecycle cost through inventory, utility, labour, and transportation. Two glycolysis recycling and landfill methodologies were examined for the end-of-life process of the product. The landfill methodology cost was calculated as higher than the cost of glycolysis recycling due to the transportation cost of waste to the landfill site, and this cost element was excluded in the LCCA of glycolysis recycling according to the data collection limitations. The results identified that the contribution of the additional materials in the recycling process significantly impacts the cost of recycling.

The findings of this study indicate several broader implications beyond the direct cost analysis. The demonstrated cost-effectiveness of glycolysis indicates clear potential as an alternative to landfilling within CE strategies, suggesting that policy measures such as recycling incentives or adjusted landfill charges could support wider adoption of this method. The ABM framework developed here is adaptable and can be applied to other insulation materials or extended to broader CE contexts to analyse economic outcomes under different technological, logistical, and regulatory conditions. The scalability of glycolysis recycling also requires further investigation, particularly regarding infrastructure needs, market potential for recovered polyols, and its integration into existing waste management systems. The results additionally offer practical guidance for both industry and policymakers. Manufacturers may reduce lifecycle and operational costs by optimising raw material ratios and improving packaging practices. Policymakers can use the insights generated by this work to design regulatory measures that encourage recycling uptake, support chemical recycling technologies, and enhance the circularity of construction materials.

This study presents a novel integration of LCCA within a single ABM framework to analyse the economic circularity of PUR-based PIR insulation. The model, developed in AnyLogic, simulates all major lifecycle stages and cost driver interactions, including recycling, landfill scenarios. This approach addresses a major gap in the existing literature, offering a structured economic circularity assessment for PUR-based PIR insulation and advancing methodological understanding of how material composition and process factors influence lifecycle costs. The model provides a practical decision-support tool for industry and policymakers by enabling detailed evaluation of PUR-based PIR insulation across its entire lifecycle. It supports sustainable material selection, cost-efficient recycling strategies and CE-aligned end-of-life decisions. Although implemented as a single-agent model, the framework is adaptable to other products and contexts, helping organisations reduce investment risks, improve supply chain visibility and strengthen strategic planning within CE applications. Future research should incorporate transportation distances and geographic factors into the ABM and LCCA to provide a more realistic representation of real-world conditions and assess the wider economic and environmental viability of alternative end-of-life options.

Limitations include the focus that was placed on the procurement prices for raw materials. Other factors, such as supply chain fluctuations, inflation, and manufacturing costs, could also be included in future research. Future research could integrate a combined economic-environmental LCCA model to provide a holistic sustainability assessment.

6. Acknowledgements

The authors confirm that this study did not involve human participants, personal data, or the use of animals. All analyses were performed using secondary data collected from publicly accessible sources and published materials.

Funding: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Declaration of generative AI in scientific writing: During the preparation of this work, the corresponding author used OpenAI GPT and Grammarly to check the grammar accuracy of approximately 200 words throughout the main body of the manuscript. After using this tool/service, the author reviewed and edited the content as needed and take(s) full responsibility for the content of the published article.

Circular Economy in Polyisocyanurate-based Insulation: Lifecycle Cost and Glycolysis Recycling Modelling

Abstract

Purpose: The purpose of this study is to evaluate the economic impact of the integration of Circular Economy (CE) principles into the recycling processes of polyisocyanurate (PIR)-based building thermal insulation.

Design/methodology/approach: The study focuses on the glycolysis recycling of PIR waste and identifies factors influencing the cost-effectiveness of polyol recovery. An agent-based model was designed for product circularity assessment and Lifecycle Cost Analysis (LCCA). The model was applied and evaluated on a polyurethane (PUR)-based PIR building thermal insulation product. Sensitivity analysis was conducted to identify and assess the sources of uncertainty within the model.

Findings: The results identified that the cost of glycolysis agents and the catalyst contributed to 62% of the cost of the polyol recovery process compared to PIR waste. This study **clarifies the role** **highlights the impact** of supplementary materials in polyol recovery. Results also highlight how excessive methylene diphenyl diisocyanate (MDI) significantly influences the cost of recycling PIR building thermal insulation.

Originality: This study provides insights into the economic feasibility and material impacts of integrating CE in PIR insulation recycling.

Practical implications: CE of the least recycled materials such as PIR is as an effective alternative to provide a sustainable economic growth and to protect against natural capital depletion.

Keywords: Circular Economy; Remanufacture; Lifecycle Cost; Agent-based modelling; Polyurethane; Thermal Insulation

1. Introduction

Thermal insulation is broadly regarded as one of the most effective measures for enhancing the energy performance of buildings by reducing heat transfer within building envelopes, leading to lower heating and cooling demand and greater overall energy efficiency (Stephan and Athanassiadis, 2017). It offers substantial advantages for both construction firms and building owners by reducing energy use, lowering associated costs, and minimising environmental

1
2
3 impacts, making it a highly favourable option across the sector (Abu-Jdayil *et al.*, 2019).
4 Polyisocyanurate (PIR) and polyurethane (PUR) insulation materials ~~have offer~~ valuable utility
5 due to their energy efficiency and potential for recyclability (Pralat *et al.*, 2023; Reinerte *et al.*,
6 2024) (Pralat *et al.*, 2023a; Reinerte *et al.*, 2024a). This performance is enhanced by the
7 insulation's long lifecycle, which eliminates the need for regular replacements and reduces
8 construction waste (Nasir *et al.*, 2017). ~~(Nasir *et al.*, 2017)~~. These insulation materials are widely
9 used in residential, commercial, and industrial buildings that require strong thermal
10 performance and adherence to fire-safety standards (Schiavoni *et al.*, 2016). Due to its strong
11 thermal performance and adherence to fire-safety standards, the use of PUR-based PIRs' use
12 has expanded with increasing adoption of high-performance building envelopes and nearly-
13 zero-energy building requirements (Pralat *et al.*, 2023). The insulation can be applied to roofs,
14 external walls, facades, and cold-storage systems (Lakatos *et al.*, 2023). However, these
15 materials ~~that are widely used in insulating buildings~~, despite their long use, often end up in
16 landfills, resulting in significant ~~generated wastewaste generated~~ after demolition or major
17 building maintenance. Handling PIR insulation waste poses technical and environmental
18 challenges due to its thermoset polymer structure, which makes it systematically demanding to
19 be reprocessed (Gahlen *et al.*, 2021). Chemical additives, layered facings, and flame retardants
20 complicate separation and treatment processes (Thiounn and Smith, 2020). During disposal,
21 PIR can generate hazardous decomposition products, and limited recycling infrastructure
22 further restricts large-scale recovery. These factors increase the cost and complexity of
23 managing PIR waste within construction supply chains (Geyer *et al.*, 2017). Handling PIR
24 waste is also a challenging process, due to resultant contaminations. PIR waste management
25 presents challenges in both developed high-income, and developing low- and middle-income
26 countries (LMCs), although for different reasons. Developed High-income countries generate
27 larger volumes of PIR waste due to widespread insulation use driven by rigorous energy-
28 efficiency standards (Mohajerani *et al.*, 2020). In contrary, developing countries LMCs
29 typically lack adequate recycling infrastructure, formal waste-collection systems, and
30 regulatory frameworks, which increases reliance on landfilling or informal disposal, which
31 consequently makes PIR waste management to be considered as a global issue that manifests
32 differently across economic contexts (Tian *et al.*, 2024). Efforts to manage these insulations
33 include the development of chemical recycling approaches such as glycolysis recycling, which
34 can recover polyols for reutilisation in polymer production (Amran *et al.*, 2021). Moreover,
35 several manufacturers have piloted take-back schemes and recycling programmes to increase
36 material recovery ratios. Policy initiatives in Europe and other countries encourage diversion

10 (Adelekan and Sharmina, 2024; Amir *et al.*, 2023; Khajuria *et al.*, 2022). ~~(Adelekan and~~
11 ~~Sharmina, 2024; Amir *et al.*, 2023; Khajuria *et al.*, 2022).~~ In 2002, approximately 376 million
12 [kilograms of PUR and PIR insulation foam were incorporated into new products](#) (Zia *et al.*,
13 2007). [Considering the utilisation of insulation materials in the production process by](#)
14 [manufacturers and consumption by customers, the concept of 6-R \(Redesign, Reduce, Reuse,](#)
15 [Repair, Recycle, and Recover\) has been brought into consideration to apply the CE concept](#)
16 (Özkan *et al.*, 2025). [From a recycling perspective, PUR and PIR insulations can be processed](#)
17 [through various recovery methods, including mechanical and chemical recycling approaches](#)
18 (Gu *et al.*, 2021). [Chemical recycling processes, such as glycolysis make it possible to recover](#)
19 [high-value polyols that can be incorporated back into the production of new insulation products](#)
20 (Lee and Jung, 2022). ~~(Kanchanapiya *et al.*, (2021) examined the economic feasibility of~~
21 ~~recycling PUR-based insulation wastes in Thailand using a single-phase glycolysis recycling~~
22 ~~and found that the regenerated polyol provides substantial financial advantages and performs~~
23 ~~correspondingly to polyols obtained from virgin material. (Adelekan and Sharmina, 2024; Amir~~
24 ~~*et al.*, 2023; Khajuria *et al.*, 2022).~~ Numerous studies examined the energy performance,
25 environmental impacts, and lifecycle assessment of incorporating PUR-based PIRs into
26 buildings; however, research addressing the economic lifecycle dimensions of these products
27 within Sustainable Development (SD) and CE frameworks has remained comparatively
28 limited. (Gigasari *et al.*, (2023) carried out a cradle-to-gate Lifecycle Assessment (LCA) **study**
29 **that focused solely on assessing carbon payback times when optimising insulation materials**
30 **for various building orientations. In ~~the~~ experimental study by (Prat *et al.*, (2023), which**
31 **examined the thermal performance of an innovative PUR-based PIR insulation, the authors did**
32 **not address cost analysis or the economic implications of their findings. This gap is likely the**
33 **result of limited emphasis on economic circularity assessments, such as Lifecycle Cost**
34 **Analysis (LCCA), within existing research, as well as a general lack of specialised expertise in**
35 **this area among researchers and industry practitioners** (Altaf *et al.*, 2024). To view PIR waste
36 as an asset, and to examine the applicability of CE principles for this material/product, this
37 study aims to conduct an LCCA of the material across its value chain. The findings provide
38 meaningful insights to construction companies, recycling firms, and [policy](#)
39 [makers](#) in the field.

The paper is organised as follows: Section 2 provides a detailed literature review of CE within the context, focusing on thermal insulation and, in particular, PUR and PIR-based insulations. Section 3 provides a succinct outline of the methods used in this research. Section 4 presents the study results and provides the calculated costs associated with the various scenarios in PIR's end-of-life, ~~and also entails followed by~~ a critical discussion, embracing nuanced elements from ~~the~~ results and assessing how they compare with the existing research. The paper is concluded in Section 5.

2. Literature Review

2.1 Circular Economy

As a response to the prevailing linear model of take-make-dispose, the Circular Economy (CE) concept has emerged as an effective approach for supporting sustainable economic growth while reducing pressure on natural resources (Osobajo *et al.*, 2022). This approach seeks to preserve and enhance the value of raw materials, natural resources, and products by retaining them within the system for as long as possible (Merli *et al.*, 2018). The development of a CE ~~strictly~~ relies on the interconnected stages of products, processes, and systems (Jayal *et al.*, 2010). A sustainable outcome cannot be achieved unless product design, production process, supply chain efficiency, management practices, and investment assessments are treated as an integrated system (Singh *et al.*, 2026). To minimise waste generation and support long-term sustainability, the 6R concept principles offer a structured approach for achieving a closed-loop system. These principles, reduce, reuse, recycle, recover, redesign, and remanufacture, guide the handling of materials throughout a product's entire lifecycle, ensuring that resources remain in circulation for as long as possible (Jawahir and Bradley, 2016). The underlying principles give rise to six practical business strategies that support CE implementation: regeneration, sharing, optimisation, looping, virtualisation, and exchange (Macarthur Foundation, 2015; Rashidian *et al.*, 2025). The housing sector, which consumes nearly 40% of all manufactured products during construction, accounts for around 35% of global energy use (Leising *et al.*, 2018; Osobajo *et al.*, 2022). Although the CE concept has been widely examined across various industries and academic fields, its application to the economic, energy efficiency, and environmental dimensions of buildings remains ~~notably~~ underexplored (Leising *et al.*, 2018). Due to its low resource efficiency, the building and construction sector produces close to 100 billion tonnes of construction and demolition waste annually, with roughly a third of this material still being landfilled, ~~highlighting which indicates~~ significant challenges for sustainable resource management (Shooshtarian *et al.*, 2024). It is widely recognised that material reuse in construction is difficult, as buildings are typically discarded at the end of their

lifespan, as reflected in the United Kingdom's annual production of around 45.8 million tonnes of demolition and construction waste (Akanbi *et al.*, 2018).

2.2 Thermal Insulation and PUR-based PIRs Materials in Buildings

Thermal insulation is widely recognised as an effective means of improving building energy efficiency, offering economic and environmental benefits for both construction firms and building owners (Lakatos *et al.*, 2023). Due to the rapid growth of energy prices and the need for thermal comfort within residential and commercial buildings, thermal insulation products are gaining more attention (Kowalczyk *et al.*, 2023). (Kowalczyk *et al.*, 2023). The deterioration of insulation in older buildings commonly leads to substantial efficiency losses, ~~underscoring the growing need for enhanced energy-saving measures~~ (Chen and Lai, 2025). Traditional insulation materials such as PUR-based insulations, cellulose, mineral wool, cork, glass wool, and polystyrene are widely used in buildings, but they can be costly and, in some cases, pose risks to the environment and human health (Mud Fadhil *et al.*, 2014). Although the use of thermal insulation in construction has increased in recent years, its production and disposal still involve substantial energy consumption and waste generation, largely due to reliance on non-renewable, fossil-based materials (Wang *et al.*, 2018). ~~PUR-based insulations such as~~ ~~As an enhanced form of PUR~~ ~~PIR~~ offer superior thermal insulation performance (Reinerte *et al.*, 2024). PIRs are among the most applied thermal insulation materials for residential and commercial thermal improvement due to their anti-flammability structure (Lazo *et al.*, 2023). (Lazo *et al.*, 2023). PIRs are generally considered green materials as they are employed to maximise energy efficiency, reduce energy bills and provide thermal comfort within commercial and residential buildings (Gahlen *et al.*, 2021; Lee and Jung, 2022). (Gahlen *et al.*, 2021; Lee and Jung, 2022). PIR is also widely used as the insulating core in factory-made sandwich panels, which typically consist of thin metal facings bonded to a light insulating core, and their overall cost structure is strongly influenced by the economic contribution of the core material (Sonnenschein, 2015). In sandwich metal panels, the materials used in the insulation core typically represent a significantly higher cost than the metal facing layers (Mamalis *et al.*, 2008). The focus on the economic lifecycle aspects of these products within the CE perspectives has been, in comparison, substantially limited. (Gigasari *et al.*, (2023). Gigasari *et al.* (2023) conducted a cradle-to-gate LCA study to investigate carbon payback time in optimising insulation materials. In an experimental study of thermal characteristics of innovative insulation made of PUR-based PIR by (Pralat *et al.*, 2023) (Pralat *et al.*, 2023b), no consideration was given to cost analysis and economic implications. The limited focus on cost

analysis in such contexts is generally due to the low interest in conducting economic circularity analysis, ~~or the lack of relevant expertise among the experts and practitioners~~ (Altaf *et al.*, 2024). ~~(Altaf *et al.*, 2024a).~~

2.3 Chemical Composition and Structural Characteristics of PUR and PIR

In the form of foam and CASEs (coatings, adhesives, sealants and elastomers), PURs account for almost 8% of total polymer-based materials produced globally (Kemona and Piotrowska, 2020). ~~(Kemona and Piotrowska, 2020a).~~ As an advanced form of PUR, the variant polyisocyanurate (PIR) has shown outstanding thermal insulation properties (Reinerte *et al.*, 2024). ~~(Reinerte *et al.*, 2024b).~~ PUR and PIR are both derived from polyurethanePUR, a plastic material formed through chemical reactions (Kingspan Ltd, 2024). ~~(Kingspan Ltd, 2024).~~ Due to the structural and compositional similarity between these two polyurethanePUR-derived products, they are named as ‘polyisocyanuratePIR-polyurethanePUR foam’ or vice versa (Qian *et al.*, 2022). ~~(Qian *et al.*, 2022).~~

2.4 Sources and Generation of PUR-based Waste

The building insulation foam waste is generally generated throughout the manufacturing, construction and demolition phases (WRAP, 2013). ~~(WRAP, 2013).~~ In addition, packaging materials associated with PUR-based PIR insulations also contribute to the overall waste stream (Morashti *et al.*, 2022). Although research specifically examining packaging impacts for these products is limited, broader studies indicate that packaging can represent a significant share of product-related material flows and has notable implications for cost and logistics efficiency (Morashti *et al.*, 2022). Most of the generated PUR foam waste is still being transformed into energy as an alternative source of fuel rather than being recycled into a new value-added product (Kanchanapiya *et al.*, 2021). ~~(Kanchanapiya *et al.*, 2021).~~ ~~Zia *et al.* (2007)~~ (Zia *et al.*, (2007)) introduced four major practices to recover and recycle polyurethanesPURs, including mechanical recycling, advanced chemical and thermochemical recycling, product recycling, and energy recovery.

At the end of their useful life, clean and undamaged PUR boards have the potential to be reused as second-hand products, maintaining the same characteristics of newly manufactured products (IBU-EPD, 2018; Kingspan Ltd, 2019a; Modesti *et al.*, 2018). ~~(IBU-EPD, 2018; Kingspan Ltd, 2019; Modesti *et al.*, 2018).~~

2.5 Recycling Technologies for PUR-based Waste

Glycolysis recycling has been the most marketed depolymerisation method of downgrading, chemically breaking and returning dead products to life by recovering their crucial primary components (Heiran *et al.*, 2021). ~~(Heiran *et al.*, 2021).~~ The main goal of recycling PUR waste

via glycolysis is to recover the primary polyol, which can be reused as a raw material for producing new PURs or branded as a fuel (Heiran *et al.*, 2021). (Heiran *et al.*, 2021).

Although mechanical recycling of PUR waste is not as sophisticated as chemical recycling, with lower costs, only 1% of the produced waste is recycled mechanically (Kanchanapiya *et al.*, 2021). (Kanchanapiya *et al.*, 2021). The glycolysis recycling of PUR waste provides the opportunity to recover polyols, as well as polyols containing isocyanates (Kanchanapiya *et al.*, 2021). (Kanchanapiya *et al.*, 2021). Currently, the glycolysis process is performed through two different methods, single-phase and split-phase, depending on the obtained mixture during the degradation process of polyols (Kanchanapiya *et al.*, 2021). (Kanchanapiya *et al.*, 2021).

One of the most influential cost categories of ~~chemically~~ chemical recycling of PUR waste is the capital cost of purchasing the required agents and catalysts throughout the process (Kanchanapiya *et al.*, 2021). (Kanchanapiya *et al.*, 2021). The potential agents and catalysts convenient for the glycolysis recycling of PUR-based waste are shown in Table .

Table I Agents and catalysts for glycolysis recycling of PUR-based waste (Source: Authors).

Crude Glycerol	=	
Refined Glycerol	=	

~~As a~~ key factor towards recycling PUR-based products through the glycolysis method, is the impurity level of the obtained polyol ~~should be examined~~, as it has a significant contribution towards the polyol mixture ratio in re-producing PUR-based insulations (Miguel-Fernández *et al.*, 2022). ~~(Miguel-Fernández *et al.*, 2022b)~~. Due to its high level of impurities, various studies have been conducted to investigate the utilisation ratio of 10%, 40%, and 70% of the recovered polyol in the polyol mixture to produce new PUR-based thermal insulations (Kemona and Piotrowska, 2020). ~~(Kemona and Piotrowska, 2020a)~~. Although extensive research examines the chemical mechanisms of glycolysis for PUR-based PIR waste, again far less attention has been given to the economic feasibility of polyol recovery, particularly the influence of glycolysis agents, catalysts, material purity, and reverse logistics requirements on overall recycling costs (Kanchanapiya *et al.*, 2021; Miguel-Fernández *et al.*, 2022; Zia *et al.*, 2007).

2.6 Landfilling and End-of-life Management of PUR-based Waste

Landfilling is still ~~being~~ commonly considered as the last disposal destination of municipal solid wastes (Vaverková, 2019). ~~(Vaverková, 2019)~~. Almost 50% of the generated PUR waste is taken through the landfilling process (Kemona and Piotrowska, 2020). ~~(Kemona and Piotrowska, 2020a)~~. Accordingly, the construction industry owns almost 35% of the landfilled waste throughout the world (DEFRA, 2023). ~~(DEFRA, 2023)~~. Landfilling of PUR products after their primary lifecycle is the most common waste treatment among ~~the~~ others (Miguel-Fernández *et al.*, 2022). ~~(Miguel-Fernández *et al.*, 2022b)~~. It has ~~less-fewer~~ environmental impacts than incineration due to PUR wastes' long lifecycle, less resource and energy consumption, and greenhouse gas emissions (Deng *et al.*, 2021). ~~(Deng *et al.*, 2021)~~. It is recommended that PURs should not be landfilled permanently; however, landfilling should be taken as a temporary solution to store the waste before taking it back for the recovery process by considering the most ~~suffieient-suitable~~ technologies (Kemona and Piotrowska, 2020). ~~(Kemona and Piotrowska, 2020a)~~. Transport distance is a major cost driver in the disposal of construction materials, and existing studies illustrated that lonanog waste-haul distances

1
2
3 significantly reduce the economic feasibility of landfill treatment due to fuel, labour, and
4 operational demands (Callao *et al.*, 2021; Kim and Jeong, 2017; Di Maria *et al.*, 2018).

5 **2.7 Product Sustainability Assessment Methods**

6
7
8 In line with the principles of **Lifecycle Assessment (LCA)**, **Lifecycle Cost Analysis (LCCA)** is
9 used to evaluate the economic sustainability of a product or system by examining capital costs,
10 operational costs, and potential savings across the entire lifecycle (Dwaikat and Ali, 2018). To
11 support clearer decision-making, this method examines the total cost of ownership of the
12 product or system from its initial stage through to end-of-life, covering 5 main phases as:
13 concept and definition, design and development, manufacturing and installation, operation and
14 maintenance, and disposal (Norman, 1990). Significant efforts have been made across multiple
15 sectors, including manufacturing, energy, aerospace, logistics, and construction to develop a
16 structured and detailed LCCA framework since the early twentieth century (Farsi *et al.*, 2020).
17 Data plays a crucial role in identifying the necessary information across a product's lifecycle
18 (Yang *et al.*, 2009). The cost structure is organised into several data input categories, which
19 include linked, unlinked, direct, indirect, variable, fixed, opportunity and sunk costs (Graddy-
20 Reed *et al.*, 2021). A substantial part of academic and institutional work on LCCA is grounded
21 in the detailed framework developed by the British Standards Institution. The BSI ISO 15686-
22 5 sets out a structured approach for evaluating the lifecycle costs of buildings and construction
23 materials, covering five key whole-life stages: planning, design, construction, operation and
24 maintenance, and end-of-life (BSI ISO15686-5, 2017). Identifying cost drivers across the full
25 lifecycle of an asset is a central component of LCCA, as it helps stakeholders understand cost
26 patterns and potential savings (NATO, 2009). During the manufacturing stage, LCCA depends
27 on factors such as product lifespan, projected sales volume, expected price variability, and the
28 anticipated total costs linked to the product (Kádárová *et al.*, 2015). Moreover, energy
29 consumption in the manufacturing stage is an important contributor to the overall lifecycle cost
30 profile of products, as material choice directly influences processing energy demand (Ivanova
31 *et al.*, 2018; Rivero-Camacho *et al.*, 2023). Transportation distance is one of the dominant cost
32 factors in transporting construction materials, with longer routes significantly increasing fuel
33 demand and overall logistics costs (Daylan and Ciliz, 2016; Kärhä *et al.*, 2024; Zgonc *et al.*,
34 2019). The installation stage represents a significant element of the overall lifecycle cost of
35 building insulation systems; however, existing research on PUR-based PIR insulation
36 predominantly concentrates on thermal performance and energy efficiency, with comparatively
37 limited analysis on the economic dimension associated with installation (Vasishta *et al.*, 2023;
38 Wiprächtiger *et al.*, 2020).

2.8 Agent-based Modelling

In recent years, Agent-based Modelling (ABM) has received increasing attention in CE research, attracting interest from academics and industry worldwide as a means of analysing and improving the profitability of economic systems. ABM has become a suitable approach for analysing complex bottom-up economic and market modelling (Bert *et al.*, 2015). ABM is widely applied across various sectors, including housing, agriculture, information technology, marketing, manufacturing, and logistics (Luo *et al.*, 2019). ABM focuses on individual units or agents, each with its own characteristics at different stages of the supply chain or lifecycle, and uses their interactions to shape and regulate the behaviour of the overall system or product (Secchi *et al.*, 2024). Agents are understood to operate with autonomy, acting independently based on the information available to them; heterogeneity, reflecting variations in characteristics such as income, preferences, and behaviour; and activity, meaning their actions influence the wider system (Rizzati and Landoni, 2024). They are goal-directed and proactive, establishing objectives beyond routine tasks, and reactive and perceptive, able to recognise and respond to environmental conditions (Fussone *et al.*, 2025). Agents also operate under bounded rationality, making reasonable decisions despite limited information, as illustrated in emergency-exit choices during a fire (Castle and Crooks, 2006). Furthermore, they are interactive and communicative, exchanging information and detecting inconsistencies, possess mobility that supports dynamic interactions within systems (Drchal *et al.*, 2019), and demonstrate learning and adaptation, adjusting behaviour based on experience to function effectively in changing environments (Li *et al.*, 2019). Within the LCA context, ABM explores how different agent characteristics shape decision-making and, in turn, influence the environmental outcomes of the overall system being analysed (Lan and Yao, 2019). (Tong *et al.*, (2023) illustrated that recycling outcomes depend strongly on the waste owner's behavioural tendencies, and their ABM successfully revealed underlying psychological patterns influencing these decisions. (Ceschi *et al.*, (2021) applied ABM to a new management policy aimed at nudging recycling behaviour and demonstrated that the model effectively captured how multi-layer agents respond across different variables. (Tian *et al.*, (2024) used ABM to design a cross-regional policy design, including a 20% improvement in recycling rates and equivalent emission reductions. In waste-related LCA, where systems involve real-time processes such as collection, sorting, and recycling, ABM supports communication among agents and variables, enabling clearer identification of system interactions and helping reduce emissions, minimise waste generation, and expand recycling opportunities (Kerdlap *et al.*, 2020). ABM is valuable because the overall behaviour of a system emerges from its individual

mechanisms, which respond differently depending on their environmental conditions, even when following the same rules, which enables the analysis of these complex and autonomous interactions (Bert *et al.*, 2015).

2.1.9 Research Gaps & Contributions to Knowledge

Among various insulation materials, PUR and PIR-based insulations are widely used due to their superior thermal performance and fire resistance (Modesti *et al.*, 2018). (Modesti *et al.*, 2018). However, despite their long lifespan, PIR and PUR insulations often end up in landfills after building demolition or renovation, contributing to significant waste accumulation and environmental concerns (Prażat *et al.*, 2023). (Prażat *et al.*, 2023b). Although the CE framework has been recognised, its integration into insulation waste management remains underexplored (Ghisellini *et al.*, 2016). (Ghisellini *et al.*, 2016). Prior studies have investigated the energy efficiency and thermal performance of building insulation materials, however, there are still gaps in assessing their economic circularity and cost-effectiveness within the CE in this context framework. Several key limitations have been identified in the literature, which are (i) most studies evaluating building insulation focus on thermal performance and energy efficiency (Gök *et al.*, 2024). (Gök *et al.*, 2024). However, there is a lack of research integrating LCCA to analyse the economic feasibility of recycling insulation materials (Nyme Uddin *et al.*, 2022). (Nyme Uddin *et al.*, 2022). (ii) There are studies on recycling PUR insulation waste, yet specific investigations into PIR-based insulation circularity and cost-effectiveness are limited (Altaf *et al.*, 2024). (Altaf *et al.*, 2024b). (iii) Existing research often lacks a complete cost assessment model covering all lifecycle phases, from production to disposal (Nugroho *et al.*, 2022). (Nugroho *et al.*, 2022). (iv) Research on glycolysis recycling of PIR insulation remains sparse, particularly regarding the economic impact of additional chemicals such as methylene diphenyl diisocyanate (MDI) and glycolysis agents on polyol recovery costs (Kemono and Piotrowska, 2020). (Kemono and Piotrowska, 2020b). (v) Although ABM is highly capable of handling complex analytical problems, its application has been concentrated mainly in fields such as electrical engineering, robotics and computer science, and building insulation analysis in the literature has been mostly performed within engineering simulation modelling platforms such as DesignBuilder, TRNSYS, AutoDesk, and EnergyPlus (Bastos Porsani *et al.*, 2023; Gök *et al.*, 2024; Pakka *et al.*, 2012; Suresh *et al.*, 2023).

This study addresses these gaps by evaluating the integration of CE principles into the lifecycle cost and recycling processes of PIR-based building thermal insulation. The key contributions are:

1. Performing a full LCCA–economic assessment of PIR insulation within a CE framework, offering insights into cost-effective recycling strategies,
2. Assessing PIR insulation’s circularity through Agent Based Modelling (ABM), which provides a novel methodological contribution to insulation waste management considering non-linearity over lifecycle stages, and
3. Investigating the lifecycle cost implications of glycolysis recycling for PIR waste, identifying the major cost contributors, including catalysts and glycolysis agents.

3. Research Methodology

3.1 Methodological Framework

We have adopted an ABM approach to examine the PIR lifecycle and examine pertinent costs. ABM provides a broad range of advantages, as it allows the comprehensive simulation of agent decision-making, capturing the nuanced behaviours of agents in different circumstances (Wu *et al.*, 2024). (Wu *et al.*, 2024). Furthermore, ABM consolidates the integration of multiple concepts within one framework, enhancing the model’s flexibility, robustness and comprehensiveness in analysing attributes of complex behaviours such as phase transitions, breaking points and perturbations (Wu *et al.*, 2024). (Wu *et al.*, 2024).

3.2 Data Collection

This study conducted secondary data collection through an extensive review of literature in scientific databases, governmental guidelines, building thermal insulation manufacturers, approved industry-related institutions, well-recognised online commercial database platforms, and approved industry-related product data sheets. Throughout the data collection process, a wide range of secondary reference materials were collected using suitable field-related keywords to search through the reference materials, including titles, abstracts, and main bodies (Figure 1).

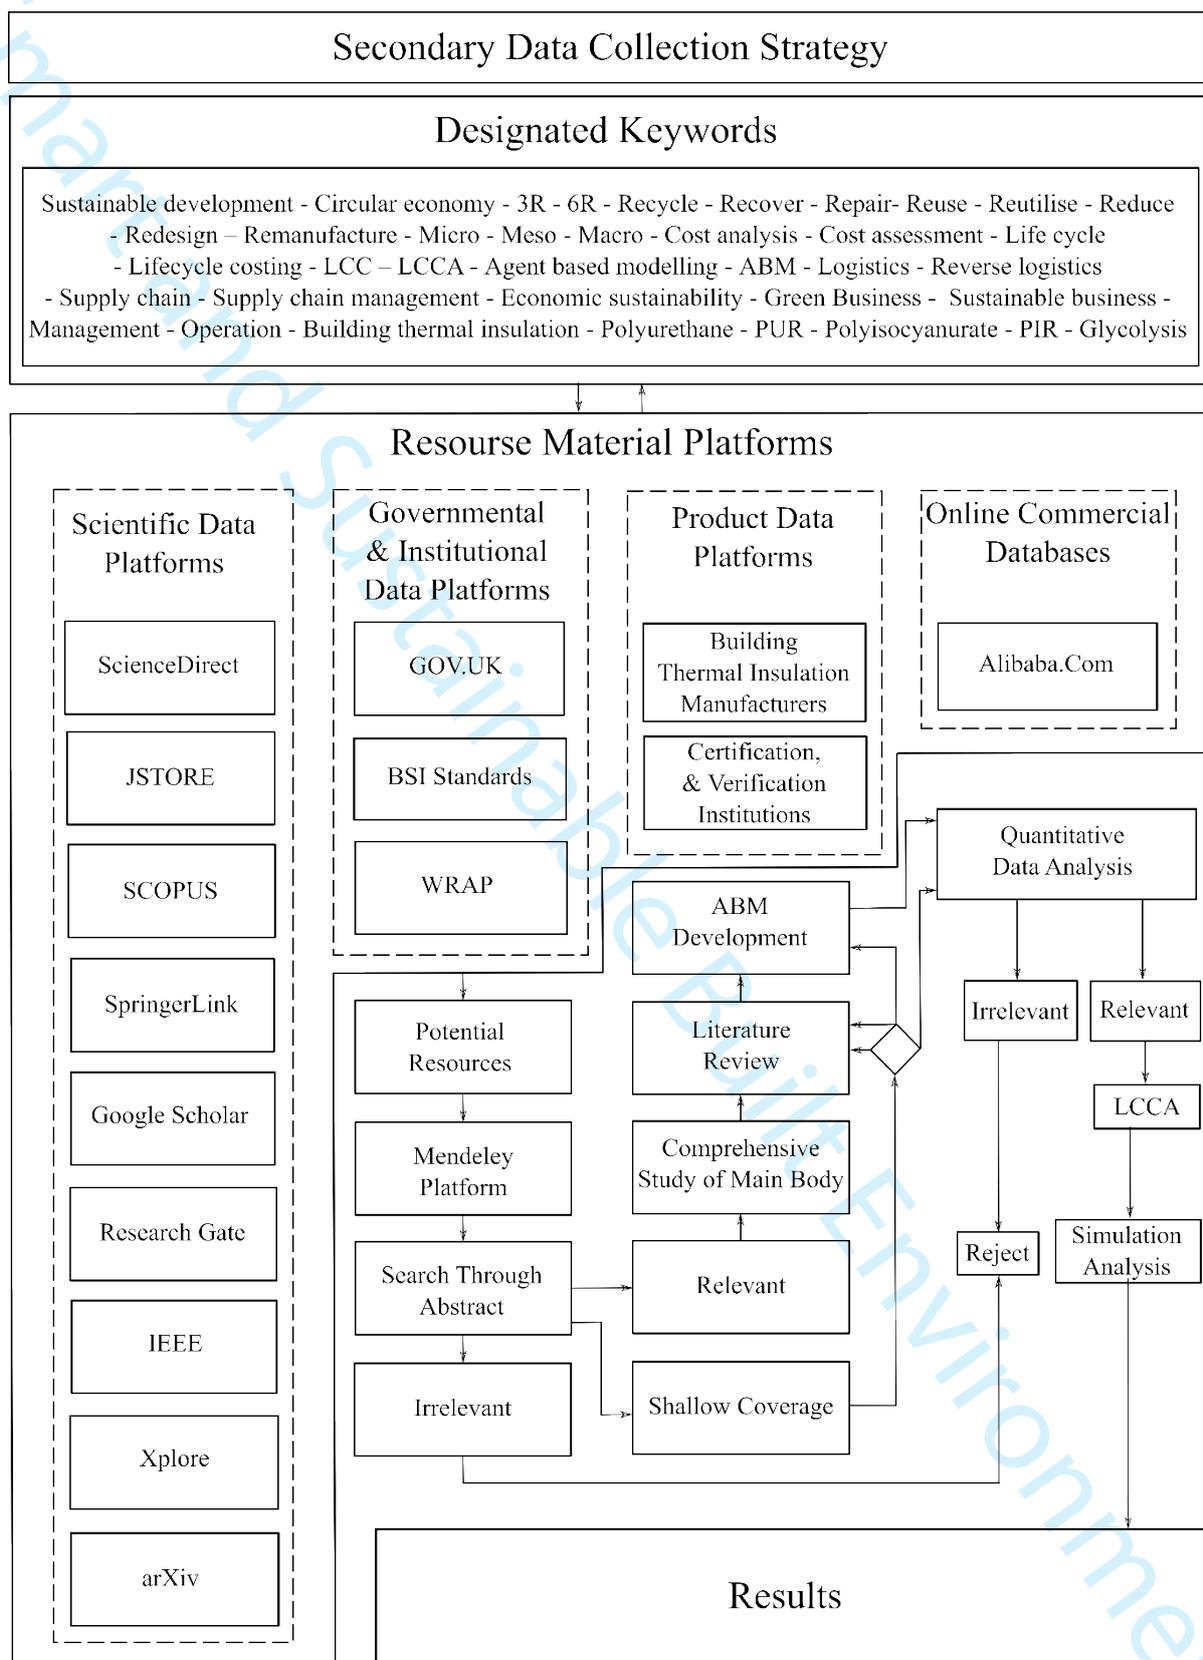

Figure 1. The data collection strategy (Source: Authors).

3.3 Scope, and Assumptions

The scope of the developed model for LCCA would be solely to consider the cost drivers and the benefits drivers are considered as input data. The future cost value was used instead of the net present value. A tactical decision was made to eliminate time from the analytical scope of this research, but to keep it only as an illustrative element for the operational interface of the product's lifecycle within the simulation model. The decision was primarily affected by the nature of the collected data for LCCA. The cost of material extraction and transport to the manufacturer was deemed out of scope. Finally, we used the British Pound (£) as the cost unit in our calculations.

It is also assumed that the unit price for the raw material acquisition in the primary lifecycle stays the same to allow the unit prices to be used within the recycling process. Along with this, a future value formula based on the lifespan of the PIR building thermal insulation, which is 75 years, is applied. Due to a lack of reliable data regarding PIR waste scraps cost, as PIR is a PUR-based product and both can be recycled with the same recycling methods, the cost of PUR scraps was calculated for the glycolysis recycling process. Moreover, it is assumed that PUR scraps are mechanically shredded into granules in the recycling plant. The mixture's recovered polyol ratio is assumed as 10%, as per literature data.

3.4 Agent-based Model Development

A novel ~~single agents~~ single-agent model was developed in AnyLogic software (v. 8.9.4) and tailored to conduct LCCA for this study's proposed product, as illustrated in Figure 2.

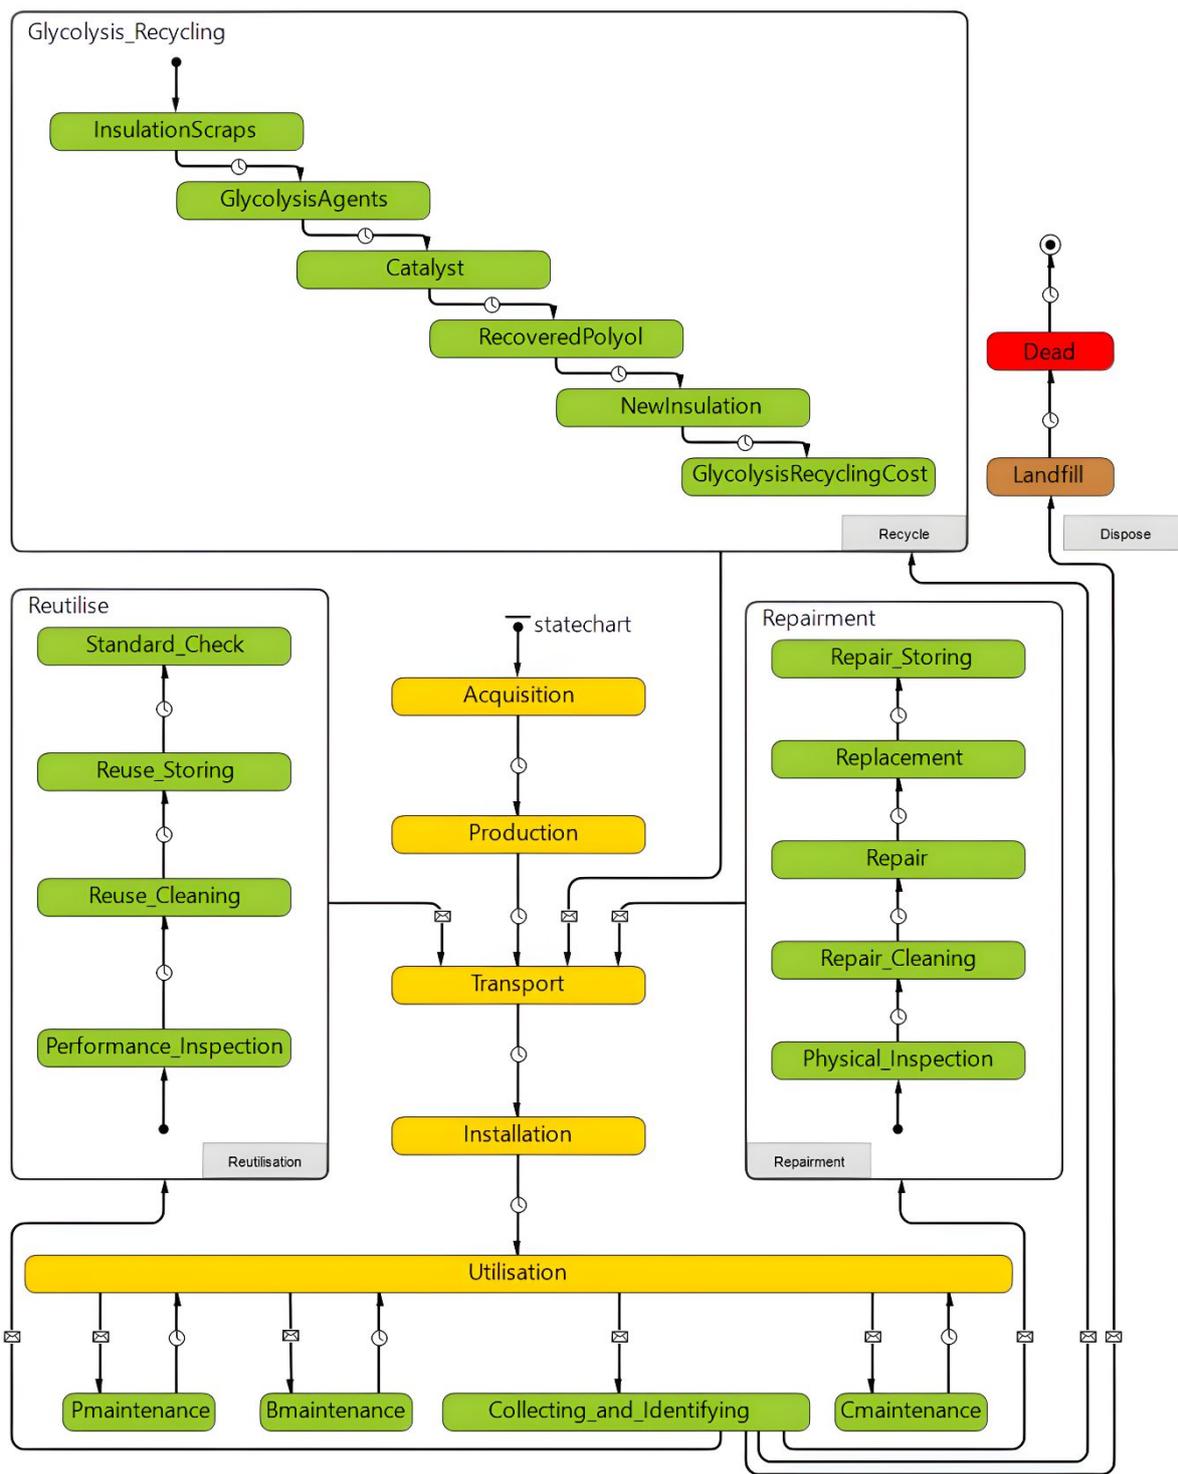

Figure 2. The developed agent-based model (Source: Authors).

The developed ABM has the potential to be tailored to other products with minor adjustments. The model includes the map of the product’s entire value chain, from raw materials procurement to green end-of-life and landfill destinations. Figure 3 illustrates the lifecycle of the PUR-based PIR building thermal insulation, and Figure 4 represents the UML state

machine diagram of this model, detailing the applied logic behind the model development in each individual state. The model consists of multiple product lifecycle stages.

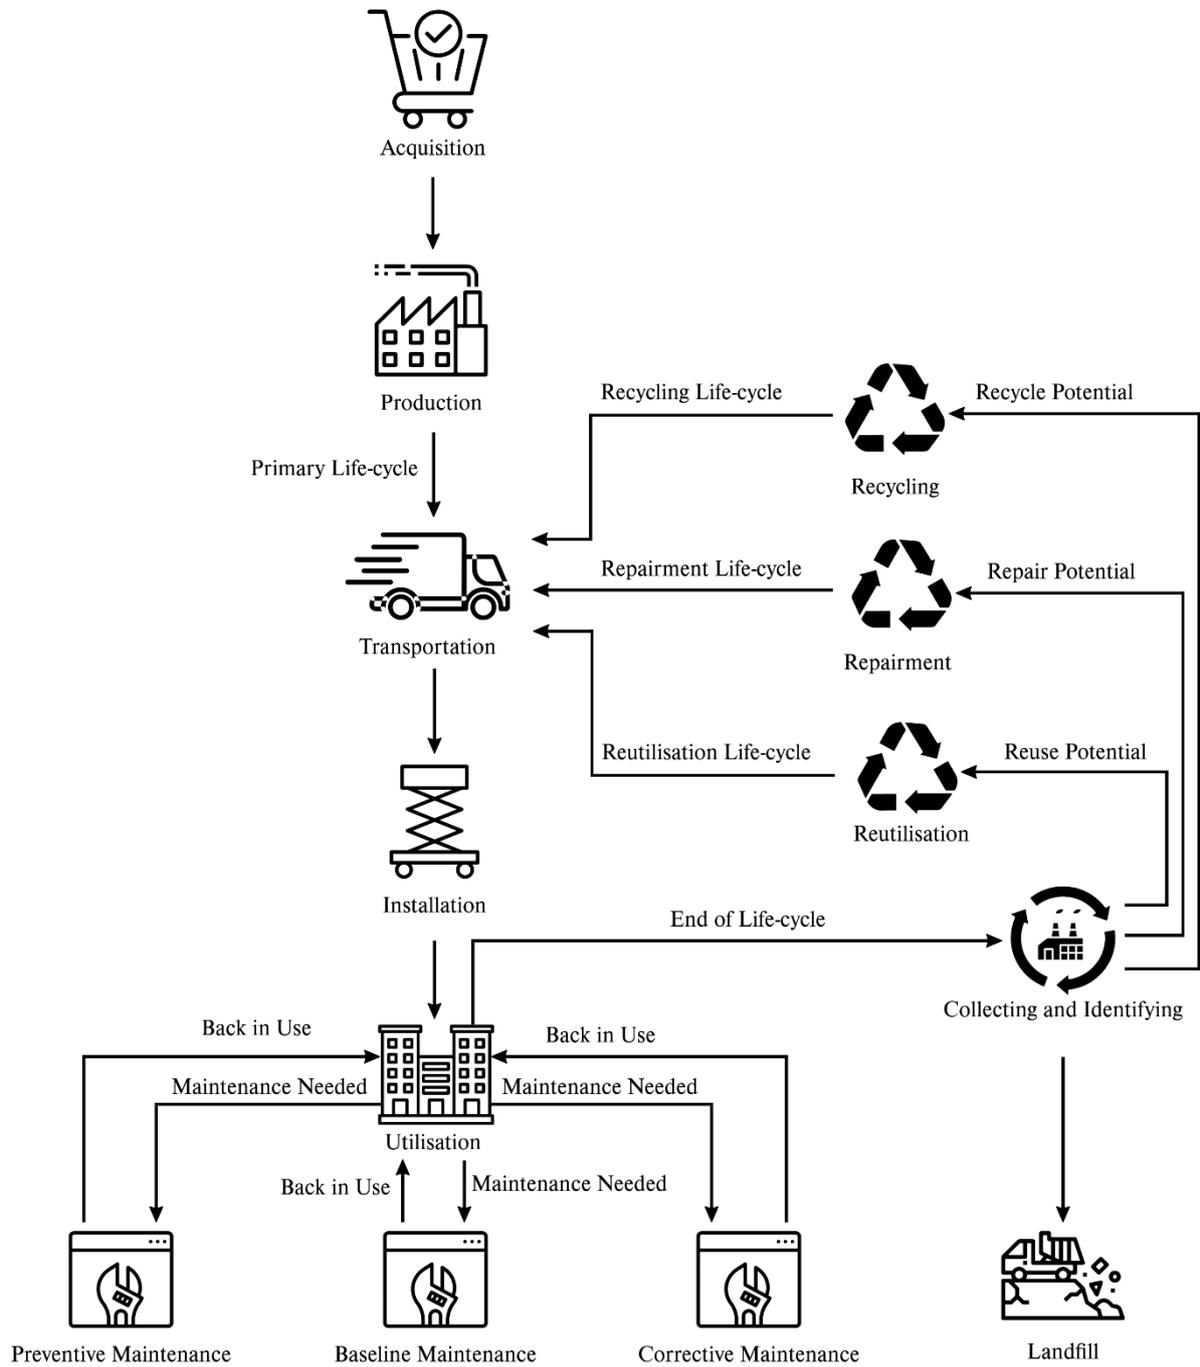

Figure 3. The modelled lifecycle stages of the PUR-based PIR building thermal insulation (Source: Authors).

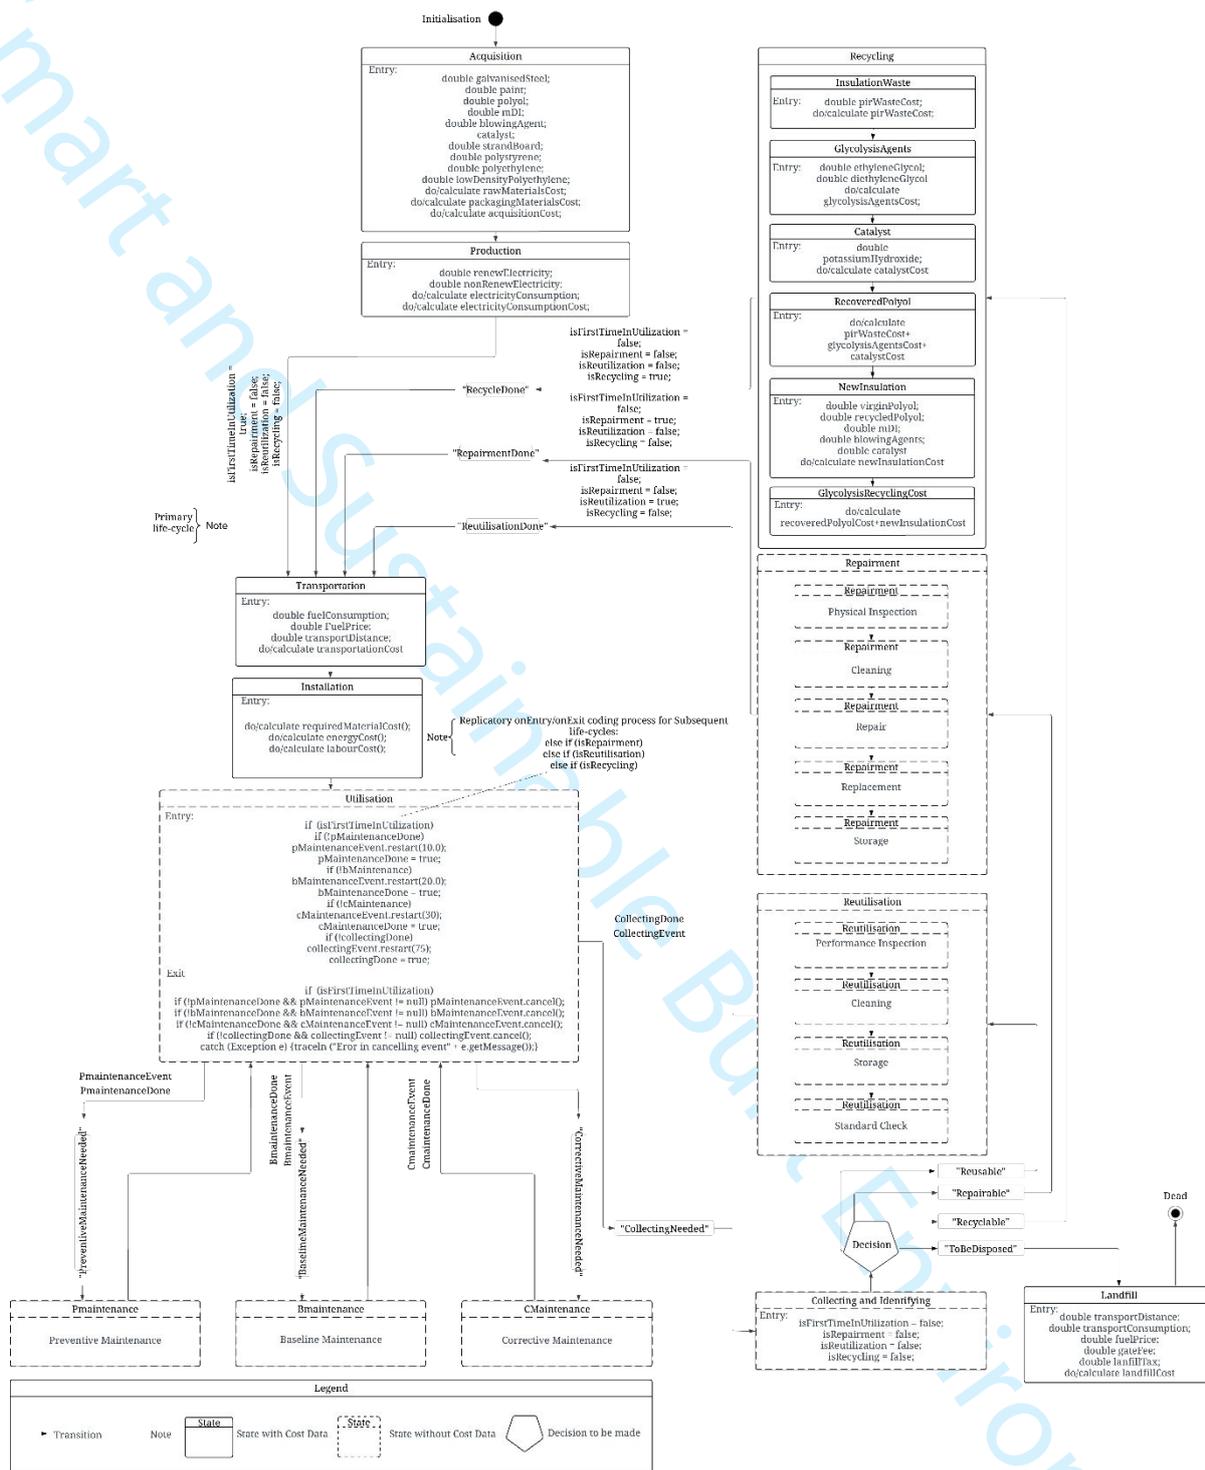

Figure 4. UML state machine diagram of the developed model for PIR building thermal insulation lifecycle (Source: Authors).

The primary lifecycle stage of the model consists of seven stand-alone stages as ‘acquisition’, ‘production’, ‘transport’, ‘installation’, ‘utilisation’, ‘maintenance’, and ‘collecting and identifying’. Once the primary lifecycle ends, four different streams are provided within the model for the product to progress through: ‘after-life reutilisation’, ‘after-life repairment’,

‘recycling’ and ‘landfill’. Three types of transitions are used in the model: transition “Timeout” only for illustration of the product’s lifecycle progression, transition by “message” between each state, and transition by “message” by sending it through a designated button, where a decision is required needs to be made. Therefore, the developed model represents the entire lifecycle of a product under real-world conditions.

3.5 Lifecycle Cost Analysis Equations

Table II illustrates the used LCCA formulas that various scholars employ in previous LCCA research projects. Although LCCA is extensively studied in a diverse and wide range of research projects, LCCA equations vary regarding the utilised symbols and equation components. But all the equations are performed in the same way and provide the same results (Altaf *et al.*, 2024a; Brealey *et al.*, 2011; Farsi *et al.*, 2020; Shankar Kshirsagar *et al.*, 2010; Shibata *et al.*, 2023; Zhang *et al.*, 2018). (Altaf *et al.*, 2024; Brealey *et al.*, 2011; Farsi *et al.*, 2020; Shankar Kshirsagar *et al.*, 2010; Shibata *et al.*, 2023; Zhang *et al.*, 2018).

Table II. Proposed Cost Model – LCCA formulations (Source: Authors).

<u>LCCA formulations</u>
$C_R = T_M \times M_P$ <p>Where, C_R = Composition Ratio; T_M = Total Mass; M_P = Mass Percentage</p>
$LCC = C_A + C_P + C_T + C_I + C$ (Each End-of-life Scenarios = C_{REC}, C_L) <p>where, LCC = Lifecycle Cost; C_A = costs of raw materials acquisitions; C_P = production costs; C_T = transportation costs; C_I = installation costs; C_{REC} = recycling costs; C_L = landfill costs.</p>
$C_A = C_{GE} + C_{PA} + C_{PO} + C_{MDI} + C_{BA} + C_C + C_{SB} + C_{PS} + C_{PF} + C_{LDP}$ <p>where, C_{GE} = cost of galvanised steel coatings; C_{PA} = cost of coating paint; C_{PO} = cost of virgin polyol; C_{MDI} = cost of methylene diphenyl diisocyanate; C_{BA} = cost of blowing agent; C_C = cost of catalyst; C_{SB} = cost of strand board for packaging; C_{PS} = cost of polystyrene for packaging; C_{PF} = cost of polyethylene film for packaging; C_{LDP} = cost of low-density polyethylene film for packaging.</p>
$C_P = C_{RE} + C_{NRE}$ <p>where, C_{RE} = cost of renewable electricity; C_{NRE} = cost of non-renewable electricity.</p>
$C_T = ((T_D * F_C) / 100) * F_P$ <p>where, T_D = transport distance; F_C = fuel consumption per 100/Km; F_P = fuel price.</p>
$C_I = C_{WBC} + C_E + C_{LAB}$ <p>where, C_{WBC} = cost of sealant; C_E = electricity cost during installation; C_{LAB} = labour costs.</p>

$$C_{REC} = C_{PIRW} + C_{EG} + C_{DG} + C_{PH} + C_P + C_{RP} + C_{MDI} + C_{BA} + C_{CAT}$$

where, C_{PIRW} = cost of PIR waste; C_{EG} = cost of ethylene glycol; C_{DG} = cost of diethylene glycol; C_{PH} = cost of potassium hydroxide; C_P = cost of virgin polyol; C_{RP} = cost of recycled polyol; C_{MDI} = cost of methylene diphenyl diisocyanate; C_{BA} = cost of blowing agent; C_{CAT} = cost of catalyst.

$$C_L = C_{TLS} + C_{GF} + C_{LT}$$

where, C_{TLS} = transport to landfill site; C_{GF} = cost of landfill gate fee /tonne/Kg; C_{LT} = cost of landfill tax /tonne/Kg.

$$FV = C_E * (1 + R)^T$$

where, FV = future value of each cost element; C_E = cost element; R = inflation rate; T = product's lifecycle period.

3.6 Secondary Data

Following a comprehensive review of various types of Environmental Product Declaration (EPD) documents for different types of building thermal insulations, it was observed that EPD documents are produced in compliance with ISO 14025, TS/14027, 1440, ISO 21930, and EN 15804 standards, and they provide generalised data about a single product or a class of products within a specific sector or industry (EPDIAB, 2024; Gibson, 2022; Kingspan Ltd, 2019a, 2023). (EPDIAB, 2024; Gibson, 2022; Kingspan Ltd, 2019, 2023). The provided data by the EPD was cross-examined with product datasheets (Kingspan Ltd, 2023). (Kingspan Ltd, 2023), and then the closest product specification for 1 (m²) was selected, as illustrated presented in Table

Table III. PIR insulated metal wall panel thermal insulation; (Source: Authors); data extracted from (Kingspan Ltd, 2019a). (Kingspan Ltd, 2019).

<u>Polyisocyanurate (PIR) Insulated Metal Wall Panel</u>		
<u>Property</u>	<u>Value</u>	<u>Unit</u>
<u>Length (m)</u>	<u>12</u>	<u>m</u>
<u>Width (m)</u>	<u>1</u>	<u>m</u>
<u>Thickness (Core 140)</u>	<u>152.4</u>	<u>mm</u>
<u>Weight</u>	<u>13.5</u>	<u>Kg</u>
<u>R-Value</u>	<u>8.44</u>	<u>(m²K)/W</u>

<u>U-Factor</u>	<u>0.11</u>	<u>W/(m²K)</u>
<u>RSL</u>	<u>75</u>	<u>Year</u>

In the first stage, the product composition data were collected to identify the required raw materials in the product's production process (Table IV).

Table IV. Product Composition Data from EPD; (Source: Authors), data sourced from (Kingspan Ltd, 2019a). (Kingspan Ltd., 2019).

<u>Product Composition (EPD)</u>		
<u>Material</u>	<u>Amount (Kg/M²)</u>	<u>Percentage of Total Mass (%)</u>
<u>Galvanised Steel</u>	<u>745.3</u>	<u>64.60 %</u>
<u>Polyisocyanurate</u>	<u>245</u>	<u>21.23 %</u>
<u>Pentane</u>	<u>16</u>	<u>1.39 %</u>
<u>Proprietary Chemicals</u>	<u>147.5</u>	<u>12.78 %</u>
<u>Product Total</u>	<u>1153.8</u>	<u>100%</u>

After collection and examination of the data, the collected values were converted to the product specifications in the datasheet, considering the weight of the product and the composition percentages, using the following proportionality formula provided in Table II.:

This proportionality calculation was followed with respect to the product's composition provided within the EPD datasheet and has been followed throughout the LCCA for each lifecycle stage section to tailor the collected data based on the chosen product's specifications (Table V).

Table V. Converted ratios for product compositions, unconverted; (Source: Authors), data sourced from (Kingspan Ltd, 2019a). (Kingspan Ltd., 2019).

<u>Converted Product Composition</u>		
<u>Material</u>	<u>Amount (Kg/M²)</u>	<u>Percentage of Total Mass (%)</u>

<u>Steel</u>	<u>8.721</u>	<u>64.60%</u>
<u>Polyisocyanurate</u>	<u>2.862</u>	<u>21.20%</u>
<u>Pentane</u>	<u>0.189</u>	<u>1.40%</u>
<u>Proprietary Chemicals</u>	<u>1.728</u>	<u>12.80%</u>
<u>Product Total</u>	<u>13.5</u>	<u>100%</u>

The same procedure was followed to calculate the material compositions for the product's packaging, as shown in Table VI.

Table VI. Product packaging compositions; (Source: Authors), data sourced from (Kingspan Ltd, 2019b). (Kingspan Ltd., 2019).

<u>Packaging Composition Data From EPD</u>		
<u>Material</u>	<u>Amount (Kg)</u>	<u>Percentage of Total Mass (%)</u>
<u>Oriented Strand Board</u>	<u>61.9</u>	<u>0.3518</u>
<u>Polystyrene</u>	<u>112</u>	<u>0.6365</u>
<u>Polyethylene Film</u>	<u>2</u>	<u>0.0114</u>
<u>Linear Low-Density Polyethylene</u>	<u>0.058</u>	<u>0.0003</u>
<u>Packaging Total</u>	<u>175.958</u>	<u>100%</u>
<u>Converted Packaging Composition Data Based on EPD</u>		
<u>Material</u>	<u>Amount (Kg)</u>	<u>Percentage of Total Mass (%)</u>
<u>Oriented Strand Board</u>	<u>4.7491</u>	<u>35.1788</u>
<u>Polystyrene</u>	<u>8.5930</u>	<u>63.6516</u>
<u>Polyethylene Film</u>	<u>0.1534</u>	<u>1.1366</u>
<u>Linear Low-Density Polyethylene</u>	<u>0.0044</u>	<u>0.0330</u>
<u>Packaging Total</u>	<u>13.5</u>	<u>100%</u>

Once the data collection for the composition part was finished, the data regarding the manufacturing stage of the product was collected based on the same methodology which was

described in previous stages. To obtain the energy consumption ratios for the product, the ratio of the product to the provided data in EPD was used. The collected data and converted rates are demonstrated in Table VII.

Table VII. Product manufacturing data (Source: Authors), data extracted from (Kingspan Ltd, 2019a)

<u>Manufacturing Data From EPD</u>			
<u>Element</u>	<u>Amount</u>	<u>Cost</u>	<u>Reference</u>
<u>Renewable primary energy consumption, excluding the renewable primary energy resources used as raw materials - Electricity (MJ)</u>	<u>3,490</u>	<u>*</u>	<u>(Kingspan Ltd, 2019a)</u>
<u>Non-renewable primary energy consumption excluding non-renewable primary energy resources used as raw materials - Electricity (MJ)</u>	<u>70,500</u>	<u>*</u>	
<u>Converted Manufacturing Data Based on EPD</u>			
<u>Element</u>	<u>Amount</u>	<u>Cost</u>	<u>Reference</u>
<u>Renewable primary energy consumption, excluding the renewable primary energy resources used as raw materials - Electricity (MJ)</u>	<u>40.83</u>	<u>*</u>	<u>*</u>
<u>Non-renewable primary energy consumption excluding non-renewable primary energy resources used as raw materials - Electricity (MJ)</u>	<u>824.88</u>	<u>*</u>	<u>*</u>
<u>MJ to kWh Conversion Factor</u>	<u>0.278</u>	<u>*</u>	<u>(Department for Energy Security & Net Zero, 2023a)</u>
<u>Electricity Tariff</u>	<u>*</u>	<u>0.19</u>	<u>(Department for Energy Security & Net Zero, 2023b)</u>
<u>Product Conversion Ratio</u>	<u>0.012</u>	<u>*</u>	<u>*</u>

Similarly, the same process was followed to collect the required data for transporting the product to the development site, which is illustrated in Table VIII.

Table VIII. Product transportation data.

<u>Transportation Data From EPD</u>			
<u>Name</u>	<u>Truck</u>	<u>Unit</u>	<u>Reference</u>
<u>Fuel Type</u>	<u>Diesel</u>	<u>*</u> <u>-</u>	<u>(Kingspan Ltd,</u> <u>2019a)</u>
<u>Litres of Fuel Consumption</u>	<u>39.0625</u>	<u>100 Km</u>	
<u>Vehicle Type</u>	<u>Heavy Duty</u> <u>Diesel</u>	<u>*</u> <u>-</u>	
<u>Transport Distance</u>	<u>554</u>	<u>Km</u>	
<u>Weight of Products Transported</u>	<u>1153</u>	<u>Kg/100m²</u>	
<u>Converted Transportation Data Based on EPD</u>			
<u>Name</u>	<u>Truck</u>	<u>Unit</u>	<u>Reference</u>
<u>Fuel Type</u>	<u>Diesel</u>	<u>*</u> <u>-</u>	<u>(Kingspan Ltd,</u> <u>2019a)</u>
<u>Litres of Fuel Consumption</u>	<u>39.0625</u>	<u>100 Km</u>	
<u>Vehicle Type</u>	<u>Heavy Duty</u> <u>Diesel</u>	<u>*</u> <u>-</u>	
<u>Transport Distance</u>	<u>554</u>	<u>Km</u>	
<u>Weight of Transported Product</u>	<u>27</u>	<u>Kg/m²</u>	
<u>Fuel Price</u>	<u>1.6</u>	<u>(£/L)</u>	

The data for the product lifecycle installation phase was collected and converted, applying the same method applied in previous sections. The data for this stage is illustrated in Table IX.

Table IVIII. Product installation data.

<u>Installation Data From EPD</u>			
<u>Name</u>	<u>Quantity</u>	<u>Unit</u>	<u>Reference</u>
<u>White butyl caulk</u>	<u>15.3</u>	<u>Kg/100m²</u>	<u>(Kingspan</u>
<u>Steel</u>			<u>Ltd,</u>
<u>Electricity</u>	<u>37.7</u>	<u>kWh/100m²</u>	<u>2019a)</u>
<u>Converted Installation Data Based on EPD</u>			
<u>Name</u>	<u>Quantity</u>	<u>Unit</u>	<u>Reference</u>
<u>White butyl caulk</u>	<u>0.3583</u>	<u>Kg/m²</u>	<u>(Kingspan</u>
<u>Steel</u>			<u>Ltd,</u>
<u>Electricity</u>	<u>0.8828</u>	<u>kWh/m²</u>	<u>2019a)</u>
<u>Labour (2 people)</u>	<u>12</u>	<u>4.5 €/m²</u>	<u>(Nyers et</u>
			<u>al., 2015)</u>

The data regarding the landfill stage of the product are ~~illustrated~~ presented in Table X.

Table IX. Product landfill data.

<u>Landfill</u>			
<u>Name</u>	<u>Parameters</u>	<u>Unit</u>	<u>Reference</u>
<u>Transport</u>	<u>Distance</u> <u>(Km)</u>	<u>50</u>	<u>(Crístiu et</u> <u>al., 2024)</u>
	<u>Fuel Price</u> <u>(1.56€/Km)</u>	<u>£69.9</u>	<u>(Department</u> <u>for Energy</u> <u>Security and</u> <u>Net Zero -</u> <u>GOV.UK,</u> <u>2023)</u>
	<u>Weight of</u> <u>Waste (Kg)</u>	<u>4.779</u>	<u>(Kingspan</u> <u>Ltd, 2019a)</u>
<u>Landfill</u>	<u>Landfill</u> <u>Gate Fee</u>	<u>75(€/tonne)</u>	<u>(WRAP,</u> <u>2023)</u>
	<u>Landfill Tax</u> <u>(€/tonne)</u>	<u>£102.00</u>	<u>(GOV.UK,</u> <u>2023)</u>

Landfill tax and landfill gate fee are not covered in EPD documents. Therefore, the official and approved rates are provided by (GOV.UK, 2023) (GOV.UK, 2023b) and WRAP [data](#) were used instead. The distance from the collection and identification to the landfill site was collected from (Cristiu *et al.*, 2024) (Cristiu *et al.*, 2024) paper as 50km as an assumption.

The cost of virgin raw material acquisition to produce PIR building thermal insulation's primary lifecycle and glycolysis recycling was collected on the Alibaba E-Commerce platform (\$/tonne), then converted to (\$/Kg), which are detailed in Table XI.

Table X. Raw material and Waste acquisition costs

Material Acquisition Cost		
Material Components	Price (\$/Kg)	Reference
Galvanised Steel Internal Face (0.75mm)	\$0.49	(Shandong Guogang Steel Group Co Ltd, 2023)
Galvanised Steel External Face (1mm)	\$0.49	
RAL 9016 - Traffic White Paint (0.1mm)	\$2.50	(Chengdu Hsinda Polymer Materials Co Ltd, 2023)
Polyol	\$2.50	(Zhongshan BASD Chemical Technology Co Ltd, 2024)
MDI	\$2.60	(Anhui Sufine Chemical Co Ltd, 2024a)
Blowing Agent: Pentane	\$3.00	(Xiamen Juda Chemical & Equipment Co Ltd, 2023)
Additives: (Chlorinated - Phosphorus Based)	\$2.18	(Jinan Juheng Chemical Co Ltd, 2023.)
Oriented Strand Board	\$12.00	(Linyi Yachen Wood Industry Co Ltd, 2023)
Polystyrene	\$1.00	(Shanghai Allwin Advanced Material Co Ltd, 2023)
Polyethylene Film	\$1.50	(Henan Talent Trading Co Ltd, 2023)
Linear Low-Density Polyethylene	\$12.80	(Shenzhen Shenhongji Packaging Material Co Ltd, 2023)

<u>Polyisocyanurate Foam</u>		
<u>Waste Excluding the</u>	<u>\$1.91</u>	<u>(FMCGTRADE, 2024)</u>
<u>Coatings</u>		
<u>Ethylene Glycol</u>	<u>\$0.95</u>	<u>(Anhui Sufine Chemical Co Ltd, 2024b)</u>
<u>Diethylene Glycol</u>	<u>\$0.80</u>	<u>(Shandong Arctic Chemical Co Ltd, 2024)</u>
<u>Potassium Hydroxide -</u>		
<u>KOH</u>	<u>\$1.20</u>	<u>(Shandong Near Chemical Co Ltd, 2024)</u>

The glycolysis agents' ratios (EG, DEG) and catalyst ratio (KOH) were used as 60/40% of the weight of the utilised waste for glycolysis agents, respectively, and 0.5% for the catalyst from which they were collected (Gu *et al.*, 2021) (Gu *et al.*, 2021). Furthermore, the ratio of the recovered polyol to the glycolysis polyol mixture from which it was collected was taken as 10/90% (Miguel-Fernández *et al.*, 2022) (Miguel-Fernández *et al.*, 2022b).

4. Results and Discussion

Table XII illustrates the total lifecycle cost, including the cost of each individual lifecycle stage of the PIR building thermal insulation, based on the two defined after-life methodologies of glycolysis recycling and product landfill.

Table XII. PIR building thermal insulation lifecycle cost.

<u>Product Lifecycle Cost Summary</u>		
<u>Lifecycle Stage</u>	<u>Without Future Cost Value (£)</u>	<u>With Future Cost Value (£)</u>
<u>Raw Material Acquisition</u>	<u>£13.60</u>	<u>*</u>
<u>Packaging Raw Material Acquisition</u>	<u>£21.50</u>	<u>*</u>
<u>Manufacturing</u>	<u>£46.41</u>	<u>*</u>
<u>Transportation</u>	<u>£346.2</u>	<u>*</u>
<u>Installation</u>	<u>£94.92</u>	<u>*</u>
<u>Glycolysis Polyol Recovery Material Acquisition</u>	<u>£6.18</u>	<u>£135.10</u>

Glycolysis New Thermal Insulation Material Acquisition	£9.26	£203.03
Landfill Costs	£31.3	£684.47
End-of-Life Destinations		
Glycolysis Recycling Method	£538.10	£860.79
Landfill Method	£553.98	£1,207.14

[The findings of this study provide a unique perspective on the economic circularity of PIR building thermal insulation, particularly through LCCA. The existing research on insulation materials has focused on thermal performance and energy efficiency, with studies relying on engineering simulations \(Gök *et al.*, 2024\) \(Gök *et al.*, 2024\).](#)

Considering the specifications of the PIR building thermal insulation, which is 12m², and its weight, which was obtained as 13.5Kg, the total cost of raw materials acquisition for the product was calculated as £13.60. MDI contributed the most to the total cost of the product, with £4.89 for 2.4Kg, which is slightly higher than the cumulative cost of galvanised steel and paint, with £4.08. Also, the cost of the external galvanised steel layer (1mm thickness) was £1.80, which was higher than the inner layer's cost of £1.35 (0.75mm thickness). This was due to the outer layer's thickness and, subsequently, more weight. The cost of polyol, with 1.5Kg weight, was obtained as £2.92, and it was followed by catalyst with £1.15 for 0.7kg weight.

[The results indicate that the cost of the raw materials used for the insulation product's core material has contributed 70% of the cost of the PIR insulation. In comparison, the cost of metal facings with paint contributed only 30% of the cost of raw material acquisitions in this section. These results align with \(Kirugulige *et al.*, 2005; Mamalis *et al.*, 2008\), who observed that in sandwich panels, the insulation core contributes the largest share of material cost compared with metal facings. This highlights the need to select core materials that balance performance with cost, and supports the CE principle of sustainable design, which seeks to maintain product efficiency across all lifecycle stages and enable reuse, repair, and recycling \(Mamalis *et al.*, 2008\).](#)

[The results discovered that the materials acquisition cost for PIR building thermal insulation packaging is 61% of the cost of the materials acquisition stage.](#) The cost of materials acquisition for the product's packaging was calculated as £21.50, slightly lower than twice the amount of raw materials acquired for the product itself. The required packaging weight for the product

was obtained as 13.5Kg. Polystyrene had the most contribution to the weight of the packaging with 8.59Kg. However, polystyrene had the lowest contribution to the total cost of packaging, with £0.79. In comparison, [the](#) lower-density polyethylene film cost was calculated as £10.08, the highest among the other contributors but with a minimal weight of 0.004Kg. Strand boards contributed to the second cost of the packaging with £9.45 ~~by 4.75Kg~~ [for 4.75 kg](#) of weight. [The findings are consistent with research showing that packaging can be a major cost driver within logistics and handling processes](#) (Morashti *et al.*, 2022). [The high packaging costs identified in this simulation highlight the need for strategic procurement decisions for PUR-based PIRs, which are lightweight, high-volume, and often require protective facings. This also aligns with CE principles of sustainable product design, where packaging choices should minimise cost and material use across all lifecycle stages while supporting efficient transport, storage, and waste management](#) (García-Arca *et al.*, 2017).

The electricity consumption cost during manufacturing was calculated as £46.4 using the MJ to kWh conversion factor. The non-renewable electricity consumption was calculated as £44.2, which was significantly higher than the cost of renewable electricity consumption, with only £2.2. [The electricity consumption results support earlier findings that manufacturing energy represents a notable indirect cost in PUR-based insulation production](#) (Rivero-Camacho *et al.*, 2023). [The small variance between raw material and electricity costs suggests that energy demand is closely tied to material selection, as different formulations require distinct reaction times and temperatures, sometimes necessitating additional additives or catalysts to maintain efficient processing.](#)

-The cost of transportation to the building development site was calculated at £346.2. The major contributor to the cost of transportation was identified as a *total* transport distance of 554-km, significantly affecting the cost of transport. Focusing on the transportation cost, ~~in~~ in the EPD document, the weight of the cargo has already been applied to the truck's fuel consumption ratio per 100 km, which is 39.06 (L/100km). [The transportation align with studies showing that transport distance is the primary driver of logistics cost for construction materials](#) (Zgonc *et al.*, 2019). [In this analysis, the 554 Km delivery route accounted for the highest cost among the primary lifecycle stages, reflecting the strong sensitivity of transport cost to distance and fuel consumption. This is consistent with evidence that lightweight but high-volume PUR-based PIRs occupy significant cargo space, which reduces loading efficiency and increases the need for additional transport trips, ultimately raising overall cost](#) (Kärhä *et al.*, 2024). [The reliance of transport operations on fossil fuels further amplifies this cost sensitivity](#) (Daylan and Ciliz,

2016). Therefore, results highlight the need for further investigation into transportation optimisation for PUR-based PIR insulation products.

The labour cost for two people significantly contributed to the installation cost of £91.80. The cost of required butyl caulk was calculated as £2.95, which was higher than the cost of electricity consumption at £0.17. Thus, the cost of PIR building thermal insulation was obtained as £94.92. This stage accounted for a notable significant proportion of the primary lifecycle cost, reflecting how installation expenses can vary with labour rates, equipment requirements and project complexity (Vasishta *et al.*, 2023; Wiprächtiger *et al.*, 2020). This is directly connected to the CE principle of optimising processes, which emphasises reducing resource utilisation, labour intensity, and operational inefficiencies throughout the entire lifecycle of the insulation. However, published research on PUR-based PIR insulation focuses largely on performance and energy outcomes, with limited attention to detailed LCCA of the installation process.

In the terms of glycolysis polyol recovery section, the total weight of needed materials for this stage was 8.8Kg. PIR waste had the maximum weight of 4.78Kg, followed by EG with 2.87Kg, DEG with 1.15Kg, and KOH with 0.01Kg. The total cost of polyol recovery through the glycolysis process is £6.18, and by considering the future value of each material for over 75 years, the glycolysis recycling's polyol recovery process was calculated as £135.10. PIR waste contributed the most to the polyol recovery cost by £2.43 and £53.12. Catalyst had the second cost contribution, which was followed by the cost of EG and DEG, respectively. The cost of the catalyst was calculated as £1.52 before and £33.35 after application of the future cost value, which was slightly higher than the cost of EG and DEG, with £1.21 and £1.02 without the future cost value, and £26.40 and £22.23 after application of the future cost value, respectively. However, based on the recovered polyol's 10% ratio within the polyol mixture, this cost element needed to be deducted from the mixture ratio cost to calculate the required virgin polyol for a new product. By adding the weight of required materials for the new PIR production process to the weight of used materials in the recovery process, the total weight required for the entire recycling process was calculated as 13.6Kg. After this Consequently, the cost of required materials to produce a new building thermal insulation (excluding the polyol recovery stage) was calculated using the same cost data for the raw material acquisition stage as £9.26 without using future cost value, and £203.03 with applying the future cost value. Therefore, the total cost of glycolysis recycling without the future value was obtained as £15.44, considering the future value of £338.13. The glycolysis results indicate that material composition strongly shapes recycling costs. MDI remains the main cost driver, and higher

1
2
3 ratios increase raw material expenditure. MDI contributes 32% due to its extra ratio in the
4 mixture compared with other materials, which is 2.4Kg. MDI is a key component broadly used
5 for chemical reactions in producing PUR-based products, and its ratio should be considered
6 during the production process, as it significantly affects the cost of material procurement. A
7 higher proportion of MDI component to achieve enhanced product capabilities and
8 characteristics in PIR insulations has an impact potential on the initial raw materials acquisition
9 costs of PIR products and, at the same time, transforms the parent variance PUR from a low-
10 cost to an expensive product with consuming more virgin materials. The cost of EG, DEG, and
11 KOH contributed to 20%, 17%, and 25% of the polyol recovery process, respectively, showing
12 their pivotal role in affecting glycolysis recycling's economic feasibility, marked by the
13 allocation of 62% of this process's cost to themselves. It should also be considered that the
14 cumulative weight of these entities, 4.03Kg, is slightly lighter than the weight of the utilised
15 PIR waste, 4.78Kg. This highlights that an increase in the volume of their utilisation ratio
16 would be extremely cost-effective. But more importantly, an excessive amount of PIR waste -
17 glycolysis agents, - and catalysts - would result in impurity ratios within the obtained polyol
18 product, which would ultimately affect the utilisation ratio of the recycled polyol within the
19 polyol mixture to produce new insulations or additional treatments should be carried out to
20 improve the impurity level of the obtained polyol (Kemona and Piotrowska, 2020; Miguel-
21 Fernández *et al.*, 2022). It should be noted that as the glycolysis process is dependent on
22 temperature; a temperature below 180°C to reduce energy consumption costs would result in
23 low catalyst activity, and a temperature above 220°C to accelerate the chemical reaction results
24 in undesired reactions, both of which would eventually result in lead to significant cost
25 increases. Therefore, recycling profitability is further constrained by reverse logistics costs,
26 particularly when waste purity is low, and by the substantial cost share of glycolysis agents and
27 catalysts, which are considered to be major determinants of feasibility (Kanchanapiya *et al.*,
28 2021; Zia *et al.*, 2007). ~~This underscores the relevance of CE principles, which emphasise
29 improving material quality, reducing process inefficiencies and enabling more cost-effective
30 recycling pathways across the product lifecycle.~~

-The cost of transport to the landfill site was calculated at £31.03. However, by applying the
future cost value ~~for over~~ 75 years, the cost significantly increased to £684.47. In the simulation
analysis, the glycolysis recycling cost was obtained as £538.10 and £860.79, which was
cheaper than the landfill by £553.98 and £1,207.14, respectively. ~~These rResults indicate that
transportation has contributed to 97% of the landfill's total cost, highlighting an additional
barrier: the transportation cost of waste to the landfill site due to the distance factor. These~~

findings align with (Kanchanapiya et al., (2021), who reported that transport costs for PUR-based PIR waste are considerably high, making distance a critical barrier to landfill feasibility. Transport costs between collection and disposal facilities directly reduce economic viability, particularly for lightweight, high-volume materials such as PUR-based PIR insulations. Longer haul distances require additional fuel, labour and equipment, ~~increasing and adds~~ both economic and ecological burdens. The sharp rise in transport costs when future values are applied reflects expected long-term fuel price fluctuations and inflation, ~~indicating indicating~~ –the value of lifecycle-based budgeting tools such as future and net present value for long-term circularity assessment.

4.1. Model Validation: OAT Sensitivity Analysis

~~In the first step of the sensitivity analysis, the glycolysis recycling process was identified as the key area likely to significantly affect the total lifecycle cost of PIR insulation, due to its multiple cost components. At the first step of conducting the sensitivity analysis, the area of this research that is expected to have a substantial impact on the output of the model, which is the total lifecycle cost of PIR building thermal insulation, was identified as the glycolysis recycling process of the product, due to containing various types of cost components.~~ The entire glycolysis recycling process of PIR insulation consists of two major states: polyol recovery and production of new PIR insulation, along with the applied future cost value for the lifespan of the PIR insulation, ~~which in this study is over~~ 75 years. Three scenarios of reducing the cost of each component by 10, 30 and 50% were developed to explore the range of possible output variations. To check the robustness of the model, the cost of PIR foam waste procurement, the cost of MDI procurement, and the cost of virgin polyol procurement were selected as the three input variables. The results of input variable manipulation were observed in the cost of glycolysis recycling and the total lifecycle cost of the product. The logic of defining three different inputs at a time and two outputs was to check the differentiation within both the local and global ranges of the input variables to outputs, along with replication processes with other inputs to increase the confidence of the model to conduct simulation analysis. The results of input cost manipulations to the outputs per percentage and by cost reductions are detailed in Figures 5. ~~and 6.~~, respectively.

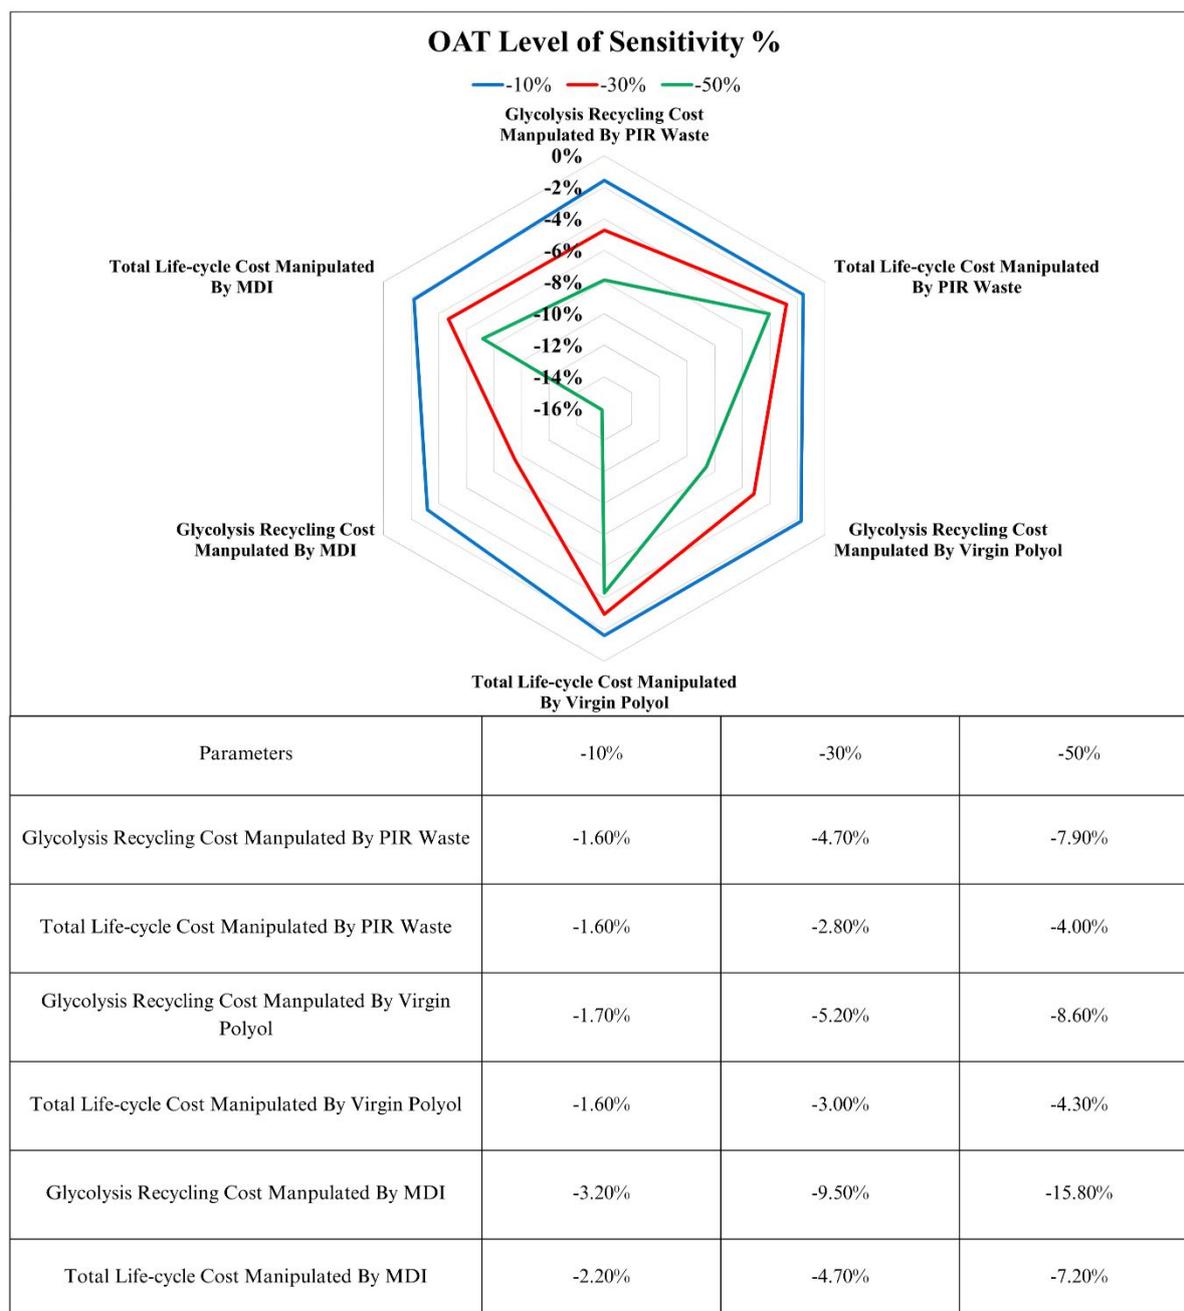

Figure 5. OAT Sensitivity Analysis Scenarios by percentage variations (-Source: Authors).

Figure 6. OAT Sensitivity Analysis Scenarios by cost variations.

According to the results, by the MDI had the highest simulation model's input manipulation potential among the others by -3.2, -9.5, and -15.8% by each of the reduction scenarios. Moreover, all the selected inputs have contributed to proportional and predicted changes in the selected outputs, indicating that the developed model is proportionally sensitive to input changes.

The findings of this study provide a unique perspective on the economic circularity of PIR building thermal insulation, particularly through LCCA. The existing research on insulation materials has focused on thermal performance and energy efficiency, with studies relying on engineering simulations (Gök *et al.*, 2024).

The results indicate that the cost of the raw materials used for the insulation product's core material has contributed 70% of the cost of the PIR insulation. In comparison, the cost of metal facings with paint contributed only 30% of the cost of raw material acquisitions in this section. The results of this simulation model align with the findings of (Kirugulige *et al.*, 2005; Mamalis *et al.*, 2008) that in the case of sandwich metal panels, the cost of utilised materials in the product's core is substantially high compared with metal facings. This directly signifies CE's sustainable design principle, illustrating that the selection of the raw materials should be incorporated with achieving optimum thermal insulation functionality and performance (throughout its entire lifecycle stages) to modify the negative economic impacts of the high cost of purchasing raw materials (Mamalis *et al.*, 2008). The results discovered that the materials acquisition cost for PIR building thermal insulation packaging is 61% of the cost of the materials acquisition stage.

Considering specific characteristics of various types of insulation products made by PUR-based materials such as PIR, which are light in weight and high in volume and sometimes contain metal facings, the results highlight the importance and cost-effectiveness of packaging as it affects the cost directly and indirectly during procurement, inventory, transportation and logistics (García-Area *et al.*, 2017; Morashti *et al.*, 2022).

In glycolysis recycling, MDI contributes 32% due to its extra ratio in the mixture compared with other materials, which is 2.4Kg. MDI is a key component broadly used for the chemical reaction in producing PUR-based products, and its ratio should be considered during the production process as it significantly affects the cost of material procurement. A higher proportion of MDI component to achieve enhanced product capabilities and characteristics in PIR insulations has an impact potential on the initial raw materials acquisition costs of PIR products and, at the same time, transforming the parent variance PUR from a low cost to an expensive product with consuming more virgin materials.

The cost of EG, DEG, and KOH contributed to 20%, 17%, and 25% of the polyol recovery process, respectively, showing their pivotal role in affecting glycolysis recycling's economic feasibility, marked by the allocation of 62% of this process's cost to themselves. It also should be considered that the cumulative weight of these entities, 4.03Kg, is slightly lighter than the weight of the utilised PIR waste, 4.78Kg. This highlights that an increase in the volume of their

1
2
3 utilisation ratio would be extremely cost-effective. But more importantly, an excessive amount
4 of PIR waste, glycolysis agents, and catalysts would result in impurity ratios within the
5 obtained polyol product, which would ultimately affect the utilisation ratio of the recycled
6 polyol within the polyol mixture to produce new insulations or additional treatments should be
7 carried out to improve the impurity level of the obtained polyol (Kemono and Piotrowska, 2020a;
8 Miguel-Fernández *et al.*, 2022b). It should be noted that as the glycolysis process is dependent on
9 temperature, a temperature below 180°C to reduce energy consumption costs would result in
10 low catalyst activity, and a temperature above 220°C to accelerate the chemical reaction results
11 in undesired reactions, both of which would eventually result in significant cost increases.
12 Results indicate that transportation has contributed to 97% of the landfill's total cost,
13 highlighting an additional barrier: the transportation cost of waste to the landfill site due to the
14 distance factor. PUR-based and PIR products are considered lightweight products with a high
15 volume. This would significantly affect transportation costs, as longer transportation distances
16 require more capital investment and extensive operational costs, such as equipment and labour
17 for reverse logistics.

28 29 30 **5. Conclusions**

31 This study presents a comprehensive economic circularity assessment of PIR-based building
32 thermal insulation, highlighting the cost implications across its lifecycle, from raw material
33 acquisition to end-of-life disposal. The results highlighted the significant role of MDI and
34 glycolysis agents in the economic feasibility of PIR recycling, with MDI contributing 32% of
35 glycolysis costs and glycolysis agents accounting for 62% of polyol recovery expenses.
36 Additionally, packaging costs were identified as a significant financial burden, **demonstrating**
37 **which demonstrates** the need for optimised supply chain strategies. The results indicated that
38 using ineffective and undesirable ratios of raw materials leads to a significant direct and
39 indirect cost increase, higher energy consumption costs, and inefficiency throughout the
40 process. Moreover, the cost of packaging products was higher than the cost of raw materials
41 for the main product, directly and indirectly impacting the product's lifecycle cost through
42 inventory, utility, labour, and transportation. Two glycolysis recycling and landfill
43 methodologies were examined for the end-of-life process of the product. The landfill
44 methodology cost was calculated as higher than the cost of glycolysis recycling due to the
45 transportation cost of waste to the landfill site, and this cost element was excluded in the LCCA
46 of glycolysis recycling according to the data collection limitations. The results identified that
47 the contribution of the additional materials in the recycling process significantly impacts the
48 cost of recycling.

1
2
3 The findings of this study indicate several broader implications beyond the direct cost analysis.
4 The demonstrated cost-effectiveness of glycolysis indicates clear potential as an alternative to
5 landfilling within CE strategies, suggesting that policy measures such as recycling incentives
6 or adjusted landfill charges could support wider adoption of this method. The ABM framework
7 developed here is adaptable and can be applied to other insulation materials or extended to
8 broader CE contexts to analyse economic outcomes under different technological, logistical,
9 and regulatory conditions. The scalability of glycolysis recycling also requires further
10 investigation, particularly regarding infrastructure needs, market potential for recovered
11 polyols, and its integration into existing waste management systems. The results additionally
12 offer practical guidance for both industry and policymakers. Manufacturers may reduce
13 lifecycle and operational costs by optimising raw material ratios and improving packaging
14 practices. Policymakers can use the insights generated by this work to design regulatory
15 measures that encourage recycling uptake, support chemical recycling technologies, and
16 enhance the circularity of construction materials.

21
22
23
24
25
26
27 This study presents a novel integration of LCCA within a single ABM framework to analyse
28 the economic circularity of PUR-based PIR insulation. The model, developed in AnyLogic,
29 simulates all major lifecycle stages and cost driver interactions, including recycling, landfill
30 scenarios. This approach addresses a major gap in the existing literature, offering a structured
31 economic circularity assessment for PUR-based PIR insulation and advancing methodological
32 understanding of how material composition and process factors influence lifecycle costs. The
33 model provides a practical decision-support tool for industry and policymakers by enabling
34 detailed evaluation of PUR-based PIR insulation across its entire lifecycle. It supports
35 sustainable material selection, cost-efficient recycling strategies and CE-aligned end-of-life
36 decisions. Although implemented as a single-agent model, the framework is adaptable to other
37 products and contexts, helping organisations reduce investment risks, improve supply chain
38 visibility and strengthen strategic planning within CE applications. Future research should
39 incorporate transportation distances and geographic factors into the ABM and LCCA to
40 provide a more realistic representation of real-world conditions and assess the wider economic
41 and environmental viability of alternative end-of-life options.

Comment	Response	Section
1. Comments from The Editor-in-Chief:		
<p>1.1 Please note that it is now mandatory for all authors to clarify the ethical approval process for studies involving human participants or animals. If necessary, you may anonymise details, such as replacing the university name with "XXX." In cases where no human participants or animals were involved, this must be explicitly stated in the acknowledgement section. Without full compliance with this requirement, your paper cannot be accepted for publication.</p>	<p>Many thanks for your comment. The required ethical approval and conflict of interest statement have now been added to the manuscript. This information is now included in Acknowledgement Section 6, clarifying that the study did not involve human participants or animals, relied exclusively on secondary, publicly available data, and that all authors declare no commercial, financial, or personal conflicts of interest.</p>	Section 6
<p>1.2 Ensure quality, consistency, and readability of the figures and associated captions. Specifically:</p> <ul style="list-style-type: none"> • Figure 1 (Data collection strategy): The text within the flowchart boxes is difficult to read due to small font size. Please increase the font size for all text elements within this figure. • Figures 2, 3, and 4 (Agent-based model diagrams): These technical diagrams require clearer labelling and higher resolution to ensure all state transitions and model components are legible. • Figures 5 and 6 (OAT Sensitivity Analysis): The axis labels and legends need to be more prominent, and ensure the percentage values and 	<p>Many thanks for this constructive feedback. All figures have now been fully revised. Larger unnecessary fonts in Figure 1 were reduced to create space for increasing smaller text to a readable size. Figures 2, 3 and 4 have been redrawn at higher resolution. Figure 6 has been removed as it was unnecessary, and Figure 5 has been replaced with a clearer sensitivity analysis diagram. Formatting, fonts and colour schemes are now consistent across all figures.</p>	The entire manuscript.

<p>cost variations are clearly visible. • All figures: Ensure consistent formatting across all figures, including font types, sizes, and colour schemes.</p>		
<p>1.3 The manuscript already includes a structured abstract with appropriate sections (Purpose, Design/methodology/approach, Findings, Originality, Practical implications, Keywords), which complies with SASBE requirements.</p>	<p>We appreciate the Editor's observation.</p>	<p>N/A</p>
<p>1.4 Consider referring to and citing where relevant articles published recently in SASBE so that the journal maintains continuity in the discourse it generates. Your paper addresses circular economy in building materials and lifecycle cost analysis, which are topics of growing interest in sustainable built environment research. Recent SASBE publications on circular economy principles, building material sustainability, and lifecycle assessment methodologies would strengthen your literature review and position your work within the journal's ongoing scholarly conversation.</p>	<p>We appreciate the Editor's observation. Recent SASBE publications have now been incorporated into the revised manuscript to strengthen the literature review and align the paper with the journal's ongoing discourse. Specifically, the following SASBE articles have been added and cited where relevant:</p> <ul style="list-style-type: none"> • Performance assessment of residential building renovation: a scientometric analysis and qualitative review of literature • Circular economy in action: the application of products with recycled content in construction projects – a multiple case study approach • A systematic review of circular economy research in the construction industry 	<p>Section 2</p>
<p>1.5 The references are incorrectly formatted, and all references need to follow the journal</p>	<p>Thank you for highlighting this. All references have now been fully revised to comply with the journal's formatting requirements. The manuscript follows</p>	<p>References</p>

<p>requirements with no exception. Follow the author guidelines for further details. Most importantly, all references should have at least one of the followings: doi, ISBN (books only), URL (even for journal articles, where there is no doi). When you are referring to URL, you must indicate the last access date. Any reference which has none of these, must be removed from the text and bibliography. ALL references must be sorted in alphabetic order.</p>	<p>the Emerald Harvard style, with every reference updated to include a DOI, ISBN, ISSN or URL with access date as required. References have also been alphabetically ordered, and entries lacking the required information have been corrected and removed.</p>	
<p>1.6 Specific issues identified in your reference list:</p> <ul style="list-style-type: none"> • Several references lack doi numbers where these are available (e.g., Adelekan and Sharmina, 2024; Altaf et al., 2024a, 2024b) • Online commercial database references (e.g., Alibaba product listings) require URLs with last access dates • Government publications (GOV.UK, DEFRA) need complete URLs with access dates • Some references appear to have incomplete information (e.g., Jinan Juheng Chemical Co Ltd with "n.d." for date) • References from Kingspan Ltd (2019) appear multiple times - ensure these are correctly distinguished if they are different documents • Check all manufacturer datasheets and ensure 	<p>We appreciate the careful attention to these, which has helped improve the accuracy and consistency of the reference list. All reference issues have now been addressed. DOI numbers have been added where available, online commercial and governmental sources now include full URLs with access dates, entries with incomplete information have been corrected, Kingspan Ltd documents have been clarified and distinguished, and all manufacturer data sheets have been reformatted according to the entire citation style.</p>	<p>References</p>

<p>proper citation format with access dates</p>		
<p>1.7 The whole paper needs some thorough proofreading before final submission. Pay particular attention to: • Consistency in terminology (e.g., "polyisocyanurate" vs "PIR", "lifecycle" vs "life-cycle") • Technical abbreviations should be defined at first use • Tables and figures should be referenced consistently in the text • Ensure smooth transitions between sections, particularly between the literature review and methodology sections.</p>	<p>Thank you for this helpful observation. All points have now been addressed. Terminology and abbreviations have been standardised, tables and figures are consistently referenced, and transitions between sections, particularly between the methodology, have been revised. The literature review has been reorganised into 9 subsections, each clarifying a specific aspect of the research and concluding with the identified and revised research gaps, creating a clear transition to the methodology section and the adopted approach used to address these gaps.</p>	<p>The entire document. Sections 2 and 3.</p>
<p>1.8 The Conclusions section of the paper lacks thought-provoking observations, elaboration on the directions for further research and future applications of the presented results. Specifically: • Expand on the policy implications of your findings regarding the cost-effectiveness of glycolysis recycling versus landfilling for PIR insulation • Discuss how your agent-based modelling approach could be applied to other building materials or circular economy contexts • Elaborate on the potential for scaling up glycolysis recycling of PIR insulation in the construction industry • Consider the role of</p>	<p>We appreciate the editor's detailed feedback regarding the need for a more substantial and forward-looking conclusion section. The conclusions have been fully revised to address all points raised. The revised section now includes:</p> <ul style="list-style-type: none"> • Clearer policy implications by explaining how the demonstrated cost-effectiveness of glycolysis recycling, compared with landfilling, can inform waste-management regulations, landfill taxation, and recycling incentives. • Expands on the applicability of the ABM, outlining how the modelling approach can be adapted to other products and wider CE scenarios across the construction sector. • Discusses the potential for scaling up glycolysis recycling, including considerations related 	<p>Section 5</p>

<p>regulatory frameworks and economic incentives in promoting circular economy practices for thermal insulation materials</p> <ul style="list-style-type: none"> • Address the limitations regarding the exclusion of transportation costs in glycolysis recycling and how this might affect real-world implementation • Provide more concrete recommendations for industry practitioners and policymakers based on your lifecycle cost analysis findings 	<p>to infrastructure requirements, the market for recovered polyols, and integration with existing waste-management systems.</p> <ul style="list-style-type: none"> • Addresses regulatory and economic drivers, highlighting how policy instruments and financial incentives could support chemical recycling adoption and promote circularity in insulation materials. • Acknowledges the limitation regarding transportation costs, noting that their exclusion from the glycolysis pathway may affect real-world cost estimations and should be incorporated in future work. • Provides recommendations for both industry and policymakers, including optimising raw material ratios, improving packaging processes, and designing regulatory frameworks that encourage recycling and chemical recovery technologies. • Outlines directions for future research, emphasising the integration of transport and geographical factors into ABM and LCCA for more accurate real-world modelling. 	
<p>1.9 When you upload your revisions, please make sure that you submit a clean version (without track-changes), a track-changes version, and a table clearly indicating all changes been made. Without this, I will need to return your revisions back to you.</p>	<p>Thank you for the clear instructions. In the revised submission, we have provided all required documents:</p> <ul style="list-style-type: none"> • A clean version of the manuscript. • A track-changes version showing all revisions. • A detailed table outlining every amendment made in response to the Editor's and reviewers' comments. 	N/A
<p>1.10 In the acknowledgements, please</p>	<p>The acknowledgements section has been added to include a clear</p>	Section 6

<p>confirm whether AI-based tools (e.g., ChatGPT, Grammarly) were used for drafting, summarising, or refining this manuscript. If AI assistance was used, specify which sections were AI-generated or AI-edited.</p>	<p>declaration of the use of AI-based tools. The revised text specifies that OpenAI ChatGPT and Grammarly were used for limited grammar refinement and that all AI-assisted content was subsequently reviewed and verified by the authors. This clarification has now been incorporated into the manuscript as requested.</p>	
2. Comments from Reviewer 1:		
<p>2.1 Page 2, line 5: Why is insulation material important in buildings? What are the challenges to handling PIR? Discuss PIR as a construction waste material. Is this a problem of developed countries or developing countries? What type of building uses this insulation? What efforts have been made to manage the waste?</p>	<p>We appreciate the reviewer's thoughtful comment for highlighting this important point. The comment has been fully addressed at the beginning of the section through line 8 of the reviewed manuscript, and the revisions are visible in the track-changes file.</p>	Section 1.
<p>2.2 Page 2, lines 8-29: What research has been conducted to apply Circular economy principles (all or few) for PIR insulation?</p>	<p>We thank the reviewer for this valuable comment. A part of the question has already been covered in the research gap section of this research project. However, an appropriate version of this section was added to the introduction section in order to fill the highlighted structural gap. Therefore, the section has now been expanded to include a detailed discussion of existing research that has applied CE principles to PIR and PUR-based insulations. The revised text (beginning of line 8 to line 29 of the manuscript) now outlines key CE strategies identified in the literature, including mechanical, chemical, thermochemical, and product recycling routes, as well as energy recovery practices. Relevant studies have been incorporated to illustrate how these methods have been applied to PUR-based PIR waste, including work on glycolysis-based polyol recovery,</p>	Section 1.

	<p>economic feasibility assessment of chemical recycling, and research on reuse and material optimisation in insulation applications. Furthermore, the revised section highlights that although CE-related research has addressed material performance, energy efficiency, and environmental impacts, the economic lifecycle dimensions within CE and SD frameworks remain underexplored. This gap motivates the present study. All changes are visible in the track-changes version of the manuscript.</p>	
<p>2.3 Section 2: Organise the literature review section-wise with proper headings. No literature on LCA and agent-based modelling.</p>	<p>We appreciate the reviewer's helpful suggestion. The literature review has been reorganised as requested and now appears in Section 2, structured into 9 subsections. This includes dedicated coverage of both LCA-related methods and ABM modelling. All revisions are visible in the track-change version of the manuscript.</p>	<p>Section 2</p>
<p>2.4 Page 8, line 17: Equation number missing.</p>	<p>The proportionality formula, along with the composition ratio it defines, has been removed from the main text and relocated to Table II.</p>	<p>Section 3.6</p>
<p>2.5 Do the authors seek permission from Kingspan Ltd to use the data? Commercial sensitivity.</p>	<p>We appreciate the reviewer's query. Permission from Kingspan Ltd was not required, as all data used in this study were obtained from publicly available sources and are fully referenced within the manuscript.</p>	<p>Entire manuscript.</p>
<p>2.6 Highlight where the CE principles were evaluated with proper discussion. Further, to what extent PIR is circular in comparison to other available insulation materials.</p>	<p>Thank you for the comment. The manuscript has now been revised to highlight where CE principles are evaluated clearly. The literature review (Section 2) has been expanded to outline CE concepts and to position PIR's recyclability, material recovery potential, and limitations relative to other insulation materials. In the results and discussion section (Section 4), CE principles are applied across the key lifecycle stages of the insulation, providing a clear assessment of its circularity characteristics. These</p>	<p>Section 4</p>

	<p>additions clarify both the degree to which PUR-based PIR aligns with CE principles and how its circular performance compares with alternative insulation products.</p>	
<p>2.7 Theoretical and practical contribution needs to be reported in the conclusion section.</p>	<p>We appreciate the reviewer's observation regarding the need to articulate the theoretical and practical contributions in the conclusion. This has now been fully addressed. The revised conclusion explicitly reports both contributions in two clearly distinguishable parts. The theoretical contribution outlines the novel integration of LCCA within an ABM framework and its value in advancing economic circularity assessment for PUR-based PIR insulation. The practical contribution highlights the model's applicability as a decision-support tool for industry and policymakers, its relevance for material selection, end-of-life strategies, and wider CE implementation. Both contributions are now presented in the final section of the manuscript.</p>	<p>Section 6</p>
<p>3. Comments from Reviewer 2:</p>		
<p>3.1 The paper primarily focuses on conducting a Life Cycle Cost Analysis (LCCA) of polyisocyanurate-based insulation. While the topic itself is interesting and relevant, the depth of the work is not sufficient for a journal publication. The study appears more like a case study rather than a piece of original research.</p>	<p>We acknowledge this concern and have strengthened the manuscript accordingly. The revised manuscript now moves beyond a case-specific LCCA and provides clear original contributions. The literature review has been expanded and restructured, covering CE principles, lifecycle sustainability, LCA context and ABM foundations. The analysis evaluates PUR-based PIR's circularity across all lifecycle stages and compares it with other insulation materials. Most importantly, the study introduces a novel integration of LCCA within a single ABM framework, offering a methodological contribution not previously applied to this product or similar insulation products. The strengthened discussion of material</p>	<p>The entire manuscript. Sections 2, 4 and 5</p>

	composition, manufacturing energy, packaging, installation, logistics and recycling increases analytical depth, ensuring the paper now meets the expectations of journal-level research.	
<p>3.2 I invite the authors to clarify how the use of agent-based modelling (ABM) constitutes a novel methodological contribution, as claimed in the manuscript. From my assessment, the main contribution lies in performing the LCCA of the PUR-based PIR building thermal insulation product — an interesting analysis in itself, but not enough to stand as a journal paper on its own. The subsequent sensitivity analysis identifies cost contributors, but again, this adds limited new insight.</p>	<p>This is a valid point. We agree that the main contribution of the paper lies in the LCCA of PIR insulation. However, the manuscript now clarifies that the use of ABM provides an additional methodological contribution. There is very limited ABM research applied to PUR-based or PIR insulation products, and almost no studies that use ABM to structure and execute an LCCA across all lifecycle stages. We have expanded the explanation in the text to show how ABM is used here to map cost drivers, simulate their interactions and evaluate circularity pathways, which distinguishes this work from a conventional LCCA-only study.</p>	<p>Section 2 & Section 4</p>
<p>3.3 I find it difficult to identify any novel or original outcomes from the ABM approach that provide information not already available in existing literature. Even Section 4 (Results and Discussion) lacks substantial discussion related to ABM beyond the sensitivity analysis.</p>	<p>Thank you for this comment. This point has already been addressed in the manuscript, where the text clarifies that ABM applications in the PUR-based PIR insulation sector are extremely limited and that almost no studies integrate ABM with LCCA in this context. The contribution of the ABM is highlighted by emphasising that very few studies combine ABM with LCCA in the PUR-based PIR insulation sector (section 2.9). The revisions make clear that the model supports a structured assessment of lifecycle costs, end-of-life scenarios and circularity implications, which strengthens the analytical depth of the study. This research examines the entire value chain of PUR-based PIR insulation that has not been mapped in the existing literature. The purpose of the sensitivity analysis was to validate the robustness</p>	<p>Section 2.1 to 2.9 – Section 4</p>

	<p>of the ABM-LCCA model and to demonstrate its responsiveness to key-driver variations across the examined product's lifecycle. The analysis confirms that the model behaves proportionally under input manipulation, supporting the reliability of the results presented in section 4. With the revised results and discussion, and expanded literature on ABM, the sensitivity analysis is now clearly positioned as an integral component that strengthens the model's analytical credibility and aligns with established ABM practices in CE-related studies.</p>	
<p>3.4 The writing quality is generally good, and the presentation is acceptable; however, there are several issues:</p> <ul style="list-style-type: none"> • The paper includes too many tables, making it difficult to follow. • Most of the figures are poor in quality and not legible, seemingly extracted directly from the software. This further reinforces the impression that the work mainly reports analysis outputs rather than deeper research findings. • In Section 2.1, the authors identify four research gaps. While these are not entirely accurate, I was expecting the paper to attempt to fill them. Unfortunately, after reading the entire manuscript, it is disappointing to find that most of these gaps have not been 	<p>Thank you for this comment.</p> <ul style="list-style-type: none"> • The tables have been revised with clearer titles and unnecessary repetitions removed. • All figures have been redrawn at higher resolution to ensure full legibility, improving clarity and strengthening their contribution to the overall research narrative rather than appearing as raw software outputs. • The revised manuscript now fully addresses all research gaps identified previously in sections 2.1 now 2.9 after revision. This includes the additional gap (v) regarding the limited use of ABM in this sector. Each gap is explicitly covered through the complete LCCA of PUR-based PIR insulation, integration of ABM to examine circularity behaviour, detailed assessment of glycolysis recycling costs, and expanded discussion of CE principles in section 4. These contributions are now clearly demonstrated in Sections 2.9, 4, and 5, indicating that all identified gaps have been 	<p>Section 2.1 to 2.9 – Section 4 – Section 5</p>

adequately addressed.	addressed.	
<p>3.5 Rather than recommending outright rejection, I suggest Major Revision to allow the authors the opportunity to:</p> <ul style="list-style-type: none"> • Address my concerns outlined above. • Clearly articulate the new contribution of this work and how it differs from existing studies. • Explicitly map the findings to the identified research gaps. • Reflect on the significance of addressing (or not addressing) these gaps — acknowledging that some gaps exist in the literature because they may not be impactful or worth pursuing. • Upgrade Figures and overall presentation of the work. <p>I would be pleased to reconsider this manuscript for publication if the authors can convincingly address and substantiate the above points.</p>	<p>The revised manuscript now clearly addresses the concerns raised and demonstrates originality, depth and full alignment with the identified research gaps. The methodological contribution is now explicit: the study integrates a complete economic circularity assessment within a single ABM framework, applied for the first time to PUR-based PIR insulation, capturing lifecycle interactions between material composition, manufacturing energy consumption, packaging, installation, logistics and glycolysis recycling in ways that conventional LCCA cannot achieve.</p> <p>The findings are now mapped to the gaps identified in section 2.9:</p> <ul style="list-style-type: none"> • Gap (i): is addressed through full LCCA across all lifecycle stages, revealing dominant cost drivers such as MDI, packaging, labour and energy. • GAP (ii): is addressed through the first comprehensive circularity analysis of PIR, demonstrating CE alignment via glycolysis recyclability. • GAP (iii): is addressed by modelling the entire value chain from production to end-of-life, including logistics and reverse logistics. • GAP (iv): is addressed through detailed analysis of glycolysis agents and catalysts, which account for 62% of polyol recovery costs and influence purity and feasibility. • GAP (v): is addressed by integrating ABM with LCCA to capture non-linear lifecycle interactions not covered in traditional modelling approaches. • The results also indicate why 	<p>The entire manuscript.</p>

	<p>some gaps persist, particularly high reverse logistic burdens, impurity management issues and costly glycolysis inputs, which limit industrial adoption. Also, CE principles analysis is now incorporated throughout the discussion, demonstrating PIR's circularity potential through sustainable design (core material dominance and MDI optimisation), resource efficiency (energy and material interactions), logistical optimisation (transport distance driving 97% of landfill cost) and looping (glycolysis consistency outperforming landfill).</p> <ul style="list-style-type: none">• All figures have been redrawn and retaken in higher resolution, redundant diagrams are removed, and tables are improved for clarity. <p>We sincerely appreciate the reviewer's detailed comments, which have directly strengthened the quality and contribution of this manuscript.</p>

Table I Agents and catalysts for glycolysis recycling of PUR-based waste (Source: Authors).

Agent Type	Catalyst Type	Reference
Ethylene Glycol (EG)	Organometallic compounds	(Miguel-Fernández <i>et al.</i> , 2022)
Hexamethylene Glycol (HDO)	Sodium Acetate (NaAc)	
Propylene Glycol (PG)	Diethanolamine (DEA)	(Amundarain <i>et al.</i> , 2022)
Diethylene Glycol (DEG)	Potassium Acetate (KAc)	
Dipropylene Glycol (DPG)	Potassium Hydroxide (KOH)	
Pentamethylene Glycol (PDO)	Dimethylaminoethanol (DMAE)	
Glycerine	Sodium Hydroxide (NaOH)	(Gu <i>et al.</i> , 2023)
Trimethylene Glycol	Lithium Octoate	(Kanchanapiya <i>et al.</i> , 2021)
Hexamethylene Glycol (HDO)	Stannous Octoate	
Tetramethylene Glycol (BDO)	Driethylenediamine (DABCO)	
Driethylenediamine (DABCO)	Zinc Acetate (ZnAc ₂)	
Crude Glycerol	-	
Refined Glycerol	-	

Table II. Proposed Cost Model – LCCA formulations (Source: Authors).

LCCA formulations	
$C_R = T_M \times M_P$	Where, C_R = Composition Ratio; T_M = Total Mass; M_P = Mass Percentage
$LCC = C_A + C_P + C_T + C_I + C$ (Each End-of-life Scenarios = C_{REC} , C_L)	where, LCC = Lifecycle Cost; C_A = costs of raw materials acquisitions; C_P = production costs; C_T = transportation costs; C_I = installation costs; C_{REC} = recycling costs; C_L = landfill costs.
$C_A = C_{GE} + C_{PA} + C_{PO} + C_{MDI} + C_{BA} + C_C + C_{SB} + C_{PS} + C_{PF} + C_{LDP}$	where, C_{GE} = cost of galvanised steel coatings; C_{PA} = cost of coating paint; C_{PO} = cost of virgin polyol; C_{MDI} = cost of methylene diphenyl diisocyanate; C_{BA} = cost of blowing agent; C_C = cost of catalyst; C_{SB} = cost of strand board for packaging; C_{PS} = cost of polystyrene for packaging; C_{PF} = cost of polyethylene film for packaging; C_{LDP} = cost of low-density polyethylene film for packaging.
$C_P = C_{RE} + C_{NRE}$	where, C_{RE} = cost of renewable electricity; C_{NRE} = cost of non-renewable electricity.
$C_T = ((T_D * F_C) / 100) * F_P$	where, T_D = transport distance; F_C = fuel consumption per 100/Km; F_P = fuel price.
$C_I = C_{WBC} + C_E + C_{LAB}$	where, C_{WBC} = cost of sealant; C_E = electricity cost during installation; C_{LAB} = labour costs.
$C_{REC} = C_{PIRW} + C_{EG} + C_{DG} + C_{PH} + C_P + C_{RP} + C_{MDI} + C_{BA} + C_{CAT}$	where, C_{PIRW} = cost of PIR waste; C_{EG} = cost of ethylene glycol; C_{DG} = cost of diethylene glycol; C_{PH} = cost of potassium hydroxide; C_P = cost of virgin polyol; C_{RP} = cost of recycled polyol; C_{MDI} = cost of methylene diphenyl diisocyanate; C_{BA} = cost of blowing agent; C_{CAT} = cost of catalyst.
$C_L = C_{TLS} + C_{GF} + C_{LT}$	where, C_{TLS} = transport to landfill site; C_{GF} = cost of landfill gate fee /tonne/Kg; C_{LT} = cost of landfill tax /tonne/Kg.
$FV = C_E * (1 + R)^T$	where, FV = future value of each cost element; C_E = cost element; R = inflation rate; T = product's lifecycle period.

Table III. PIR insulated metal wall panel thermal insulation, (Source: Authors). data extracted from (Kingspan Ltd, 2019a)

Polyisocyanurate (PIR) Insulated Metal Wall Panel		
Property	Value	Unit
Length (m)	12	m
Width (m)	1	m
Thickness (Core 140)	152.4	mm
Weight	13.5	Kg
R-Value	8.44	(m ² K)/W
U-Factor	0.11	W/(m ² K)
RSL	75	Year

Table IIV. Product Composition Data from EPD, (Source: Authors), data sourced from (Kingspan Ltd, 2019a).

Product Composition (EPD)		
Material	Amount (Kg/M²)	Percentage of Total Mass (%)
Galvanised Steel	745.3	64.60 %
Polyisocyanurate	245	21.23 %
Pentane	16	1.39 %
Proprietary Chemicals	147.5	12.78 %
Product Total	1153.8	100%

Table V. Converted ratios for product compositions, unconverted (Source: Authors), data sourced from (Kingspan Ltd, 2019a)

Converted Product Composition		
Material	Amount (Kg/M²)	Percentage of Total Mass (%)
Steel	8.721	64.60%
Polyisocyanurate	2.862	21.20%
Pentane	0.189	1.40%
Proprietary Chemicals	1.728	12.80%
Product Total	13.5	100%

Table VI. Product packaging compositions (Source: Authors), data sourced from (Kingspan Ltd, 2019b).

Packaging Composition Data From EPD		
Material	Amount (Kg)	Percentage of Total Mass (%)
Oriented Strand Board	61.9	0.3518
Polystyrene	112	0.6365
Polyethylene Film	2	0.0114
Linear Low-Density Polyethylene	0.058	0.0003
Packaging Total	175.958	100%
Converted Packaging Composition Data Based on EPD		
Material	Amount (Kg)	Percentage of Total Mass (%)
Oriented Strand Board	4.7491	35.1788
Polystyrene	8.5930	63.6516
Polyethylene Film	0.1534	1.1366
Linear Low-Density Polyethylene	0.0044	0.0330
Packaging Total	13.5	100%

Table VII. Product manufacturing data.

Manufacturing Data From EPD			
Element	Amount	Cost	Reference
Renewable primary energy consumption, excluding the renewable primary energy resources used as raw materials - Electricity (MJ)	3,490	*	(Kingspan Ltd, 2019a)
Non-renewable primary energy consumption excluding non-renewable primary energy resources used as raw materials - Electricity (MJ)	70,500	*	
Converted Manufacturing Data Based on EPD			
Element	Amount	Cost	Reference
Renewable primary energy consumption, excluding the renewable primary energy resources used as raw materials - Electricity (MJ)	40.83	*	*
Non-renewable primary energy consumption excluding non-renewable primary energy resources used as raw materials - Electricity (MJ)	824.88	*	*
MJ to kWh Conversion Factor	0.278	*	(Department for Energy Security & Net Zero, 2023a)
Electricity Tariff	*	0.19	(Department for Energy Security & Net Zero, 2023b)
Product Conversion Ratio	0.012	*	*

Table VIII. Product transportation data.

Transportation Data From EPD			
Name	Truck	Unit	Reference
Fuel Type	Diesel	*	(Kingspan Ltd, 2019a)
Litres of Fuel Consumption	39.0625	100 Km	
Vehicle Type	Heavy Duty Diesel	*	
Transport Distance	554	Km	
Weight of Products Transported	1153	Kg/100m ²	
Converted Transportation Data Based on EPD			
Name	Truck	Unit	Reference
Fuel Type	Diesel	*	(Kingspan Ltd, 2019a)
Litres of Fuel Consumption	39.0625	100 Km	
Vehicle Type	Heavy Duty Diesel	*	
Transport Distance	554	Km	
Weight of Transported Product	27	Kg/m ²	
Fuel Price	1.6	(£/L)	(Department for Energy Security and Net Zero - GOV.UK, 2023)

Table IVIII. Product installation data.

Installation Data From EPD			
Name	Quantity	Unit	Reference
White butyl caulk	15.3	Kg/100m ²	(Kingspan Ltd,
Steel			2019a)
Electricity	37.7	kWh/100m ²	
Converted Installation Data Based on EPD			
Name	Quantity	Unit	Reference
White butyl caulk	0.3583	Kg/m ²	(Kingspan Ltd,
Steel			2019a)
Electricity	0.8828	kWh/m ²	
Labour (2 people)	12	4.5 €/m ²	(Nyers <i>et al.</i> , 2015)

Table IX. Product landfill data

Landfill			
Name	Parameters	Unit	Reference
Transport	Distance (Km)	50	(Crístiu <i>et al.</i> , 2024)
	Fuel Price (1.56£/Km)	£69.9	(Department for Energy Security and Net Zero - GOV.UK, 2023)
	Weight of Waste (Kg)	4.779	(Kingspan Ltd, 2019a)
Landfill	Landfill Gate Fee	75(£/tonne)	(WRAP, 2023)
	Landfill Tax (£/tonne)	£102.00	(GOV.UK, 2023)

Table X. Raw material and Waste acquisition costs

Material Acquisition Cost		
Material Components	Price (\$/Kg)	Reference
Galvanised Steel Internal Face (0.75mm)	\$0.49	(Shandong Guogang Steel Group Co Ltd, 2023)
Galvanised Steel External Face (1mm)	\$0.49	
RAL 9016 - Traffic White Paint (0.1mm)	\$2.50	(Chengdu Hsinda Polymer Materials Co Ltd, 2023)
Polyol	\$2.50	(Zhongshan BASD Chemical Technology Co Ltd, 2024)
MDI	\$2.60	(Anhui Sufine Chemical Co Ltd, 2024a)
Blowing Agent: Pentane	\$3.00	(Xiamen Juda Chemical & Equipment Co Ltd, 2023)
Additives: (Chlorinated - Phosphorus Based)	\$2.18	(Jinan Juheng Chemical Co Ltd, n.d.)
Oriented Strand Board	\$12.00	(Linyi Yachen Wood Industry Co Ltd, 2023)
Polystyrene	\$1.00	(Shanghai Allwin Advanced Material Co Ltd, 2023)
Polyethylene Film	\$1.50	(Henan Talent Trading Co Ltd, 2023)
Linear Low-Density Polyethylene	\$12.80	(Shenzhen Shenhongji Packaging Material Co Ltd, 2023)
Polyisocyanurate Foam Waste Excluding the Coatings	\$1.91	(FMCGTRADE, 2024)
Ethylene Glycol	\$0.95	(Anhui Sufine Chemical Co Ltd, 2024b)
Diethylene Glycol	\$0.80	(Shandong Arctic Chemical Co Ltd, 2024)
Potassium Hydroxide - KOH	\$1.20	(Shandong Near Chemical Co Ltd, 2024)

Smart and Sustainable Built Environment

Table XII. PIR building thermal insulation lifecycle cost

Product Lifecycle Cost Summary		
Lifecycle Stage	Without Future Cost Value (£)	With Future Cost Value (£)
Raw Material Acquisition	£13.60	*
Packaging Raw Material Acquisition	£21.50	*
Manufacturing	£46.41	*
Transportation	£346.2	*
Installation	£94.92	*
Glycolysis Polyol Recovery Material Acquisition	£6.18	£135.10
Glycolysis New Thermal Insulation Material Acquisition	£9.26	£203.03
Landfill Costs	£31.3	£684.47
End-of-Life Destinations		
Glycolysis Recycling Method	£538.10	£860.79
Landfill Method	£553.98	£1,207.14
